The dCache Book

for 1.9.12-series (FHS layout)
Abstract

The dCache Book is the guide for administrators of dCache systems. The first part describes the installation of a simple single-host dCache instance. The second part describes the components of dCache and in what ways they can be configured. This is the place for finding information about the role and functionality of components in dCache as needed by an administrator. The third part contains solutions for several problems and tasks which might occur during operating of a dCache system. Finally, the last two parts contain a glossary and a parameter and command reference.

Each release of dCache is available in two file layouts: FHS and opt. The FHS layout has files located according to the Filesystem Hierarchy Standard [http://www.pathname.com/fhs/]. Most modern distributions have adopted the FHS, so we recommend that fresh installations of dCache used this layout.

The opt layout places all the files in /opt/d-cache directory. This is where previous versions of dCache located all the packaged files. The opt layout is provided for backwards compatibility and to satisfy those sites that cannot use the FHS layout.

Looking for help? .............................................................................. viii

Welcome to the dCache. dCache is a distributed storage solution for storing huge amounts of data without a hard limit, used to provide storage in the petabyte range. Therefore it qualifies as the storage system supporting data intensive experiments.

dCache is a joined effort between the Deutsches Elektronen-Synchrotron (DESY) in Hamburg, Nordic Data Grid Facility (NDGF based in Copenhagen), the Fermi National Accelerator Laboratory near Chicago with significant distributions and support from the University of California, San Diego, INFN, Bari as well as Rutherford Appleton Laboratory, UK and CERN in Geneva.

dCache can use hierarchical storage management (e.g., hard disk and tape), provides mechanisms to automatically increase performance and balance loads, increase resilience and availability. It also supplies advanced control systems to manage data as well as data flows. Normal filesystem (btrfs, ext4, XFS, ZFS) is used to store data on storage nodes. There are several ways of accessing data stored in dCache:

- NFS 4.1 (Chimera)
- HTTP and WebDAV
- GridFTP (GSI-FTP)
- xrootd
- SRM (versions 1.1 and 2.2)
- dCap and GSIIdCap

dCache supports certificate based authentication through the Grid Security Infrastructure used in GSI-FTP, GSIIdCap transfer protocols and the SRM management protocol. Certificate authentication is also available for HTTP and WebDAV. dCache also supports fine-grain authorization with support for POSIX file permissions and NFS-style access control lists. Other features of dCache are:

- Resilience and high availability can be implemented in different ways by having multiple replicas of the same files.
- Easy migration of data via the migration module.
- A powerful cost calculation system that allows to control the data flow (reading and writing from/to pools, between pools and also between pools and tape).
- Load balancing and performance tuning by hot pool replication (via cost calculation and replicas created by pool-to-pool-transfers).
- Space management and support for space tokens.
- Garbage collection of replicas, depending on their flags, age, et cetera.
• Detailed logging and debugging as well as accounting and statistics.

• XML information provider with detailed live information about the cluster.

• Scriptable administration interface with a terminal-based front-end.

• Web-interface with live information of the most important information.

• Ensuring data integrity through checksumming.

dCache / SRM can transparently manage data distributed among dozens of disk storage nodes (sometimes distributed over several countries). The system has shown to significantly improve the efficiency of connected tape storage systems, by caching, gather and flush and scheduled staging techniques. Furthermore, it optimizes the throughput to and from data clients by dynamically replicating datasets on the detection of load hot spots. The system is tolerant against failures of its data servers, which allows administrators to deploy commodity disk storage components.

Access to the data is provided by various standard protocols. Furthermore the software comes with an implementation of the Storage Resource Manager protocol (SRM), which is an open standard for grid middleware to communicate with site specific storage fabrics.

Who should read this book?

This book is primarily targeted at system administrators.

Minimum System Requirements?

For minimal test installation:

• Hardware: contemporary CPU, 1 GiB of RAM, 100 MiB free harddisk space

• Software: Oracle/Sun Java, Postgres SQL Server

For a high performance Grid scenario the hardware requirements highly differ, which makes it impossible to provide such parameters here. However, if you wish to setup a dCache-based storage system, just let us know and we will help you with your system specifications. Just contact us: <support@dcache.org>.

What is inside?

This book shall introduce you to dCache and provide you with the details of the installation. It describes configuration, customization of dCache as well as the usage of several protocols that dCache supports. Additionally, it provides cookbooks for standard tasks.

Here is an overview part by part:

Part 1, Getting started: This part introduces you to the cells and domain concept in dCache. It provides a detailed description of installing, the basic configuration, and upgrading dCache.

Part 2, Configuration of dCache: Within this part the configuration of several additional features of dCache is described. They are not necessary to run dCache but will be needed by some users depending on their requirements.
Part 3, Cookbook: This part comprises guides for specific tasks a system administrator might want to perform.

**Looking for help?**

This part gets you all the help that you might need:

- For acquiring resources:
  - The download page [http://www.dcache.org/downloads].

- For getting help during installation:
  - Developers <support@dcache.org>

- Additional Support:
  - German support:<german-support@dcache.org>
  - UK support:<GRIDPP-STORE@JISCMAIL.AC.UK>
  - USA support:<osg-storage@opensciencegrid.org>
  - User Forum: <user-forum@dcache.org>

- For features that you would like to see in dCache or bugs that should be fixed: Just write an e-mail to <support@dcache.org>

- If you like to stay up-to-date about new releases you can use the RSS feeds available from our downloads page [http://www.dcache.org/downloads].

- For EMI releases of dCache please visit the EMI dCache download page [http://www.eu-emi.eu/releases].

   The Admin Interface ........................................................................................................ 23

This part is intended for people who are new to dCache. It gives an introduction to dCache, including how to configure a simple setup, and details some simple and routine administrative operations.
Chapter 1. Introduction

dCache is a distributed storage solution. It organises storage across computers so the combined storage can be used without the end-users being aware of where their data is stored. They simply see a large amount of storage.

Because end-users do not need to know on which computer their data is stored, it can be migrated from one computer to another without any interruption of service. As a consequence, (new) servers may be added to or taken away from the dCache storage cluster at any time.

dCache supports requesting data from a tertiary storage system. Such systems typically store data on magnetic tapes instead of disks, which must be loaded and unloaded using a tape robot. The main reason for using tertiary storage is the better cost-efficiency, archiving a very large amount of data on rather inexpensive hardware. In turn the access latency for archived data is significantly higher.

dCache also supports many transfer protocols (allowing users to read and write to data). These have a modular deployment, allowing dCache to support expanded capacity by providing additional front-end machines.

Another performance feature of dCache is hot-spot data migration. In this process, dCache will detect when files are requested very often. If this happens, dCache can generate duplicates of the popular files on other computers. This allows the load to be spread across multiple machines, so increasing throughput.

The flow of data within dCache can also be carefully controlled. This is especially important for large sites as chaotic movement of data may lead to suboptimal usage. Instead, incoming and outgoing data can be marshaled so they use designated resources guaranteeing better throughput and improving end-user experience.

dCache provides a comprehensive administrative interface for configuring the dCache instance. This is described in the later sections of this book.

Cells and Domains

dCache, as distributed storage software, can provide a coherent service using multiple computers or nodes (the two terms are used interchangeable). Although dCache can provide a complete storage solution on a single computer, one of its strengths is the ability to scale by spreading the work over multiple nodes.

A cell is dCache’s most fundamental executable building block. Even a small dCache deployment will have many cells running. Each cell has a specific task to perform and most will interact with other cells to achieve it.

Cells can be grouped into common types; for example, pools, doors. Cells of the same type behave in a similar fashion and have higher-level behaviour (such as storing files, making files available). Later chapters will describe these different cell types and how they interact in more detail.

There are only a few cells where (at most) only a single instance is required. The majority of cells within a dCache instance can have multiple instances and dCache is designed to allow load-balancing over these cells.

A domain is a container for running cells. Each domain runs in its own Java Virtual Machine (JVM) instance, which it cannot share with any other domain. In essence, a domain is a JVM with the additional functionality necessary to run cells (such as system administration and inter-cell communication). This
also implies, that a node’s resources, such as memory, available CPU and network bandwidth, are shared among several domains running on the same node.

dCache comes with a set of domain definitions, each specifying a useful set of cells to run within that domain to achieve a certain goal. These goals include storing data, providing a front-end to the storage, recording file names, and so on. The list of cells to run within these domains are recommended deployments: the vast majority of dCache deployments do not need to alter these lists.

A node is free to run multiple domains, provided there’s no conflicting requirement from the domains for exclusive access to hardware. A node may run a single domain; but, typically a node will run multiple domains. The choice of which domains to run on which nodes will depend on expected load of the dCache instance and on the available hardware. If this sounds daunting, don’t worry: starting and stopping a domain is easy and migrating a domain from one node to another is often as easy as stopping the domain on one node and starting it on another.

dCache is scalable storage software. This means that (in most cases) the performance of dCache can be improved by introducing new hardware. Depending on the performance issue, the new hardware may be used by hosting a domain migrated from a overloaded node, or by running an additional instance of a domain to allow load-balancing.

Most cells communicate in such a way that they don’t rely on in which domain they are running. This allows a site to move cells from one domain to another or to create new domain definitions with some subset of available cells. Although this is possible, it is rare that redefining domains or defining new domains is necessary. Starting or stopping domains is usually sufficient for managing load.

**Figure 1.1. The dCache Layer Model**

The layer model shown in Figure 1.1, “The dCache Layer Model” gives an overview of the architecture of the dCache system.
Chapter 2. Installing dCache

The first section describes the installation of a fresh dCache instance using RPM files downloaded from the dCache home-page [http://www.dcache.org]. It is followed by a guide to upgrading an existing installation. In both cases we assume standard requirements of a small to medium sized dCache instance without an attached tertiary storage system. The third section contains some pointers on extended features.

Installing a dCache instance

In the following the installation of a dCache instance will be described. The Chimera name space provider, some management components, and the SRM need a PostgreSQL server installed. We recommend running this PostgreSQL on the local node. The first section describes the configuration of a PostgreSQL server. After that the installation of Chimera and of the dCache components will follow. During the whole installation process root access is required.

Prerequisites

In order to install dCache the following requirements must be met:

• An RPM-based Linux distribution is required for the following procedure. For Debian derived systems the RPM may be converted to a DEB using alien. Solaris is supported using either the Solaris package or the tarball.

• dCache requires Java 1.6 JRE. Please use Sun JVM at the latest patch-level (at the moment of writing this is 1.6.0_25) and make sure to upgrade to the newest version frequently. It is recommendet to use JDK as dCache scripts can make use of some extra features that JDK provides to gather more diagnostic information (heap-dump, etc). This helps when tracking down bugs.

• PostgreSQL must be installed and running. See the section called “Installing a PostgreSQL Server” for more details. PostgreSQL version 8.3 or later is required.

Installation of the dCache Software

The RPM packages may be installed right away, for example using the command:

```
[root] # rpm -ivh dcache-server-version.noarch.rpm
```

The actual sources lie at http://www.dcache.org/downloads.shtml. To install for example Version 1.9.12-1 of the server you would use this:

```
[root] # rpm -ivh http://www.dcache.org/downloads/1.9/dcache-server-1.9.12-1.noarch.rpm
```

The client can be found in the download-section of the above url, too.

Readying the PostgreSQL server for the use with dCache

Using a PostgreSQL server with dCache places a number of requirements on the database. You must configure PostgreSQL for use by dCache and create the necessary PostgreSQL user accounts and database structure. This section describes how to do this.
Enabling local trust

Perhaps the simplest configuration is to allow password-less access to the database and the following documentation assumes this is so.

To allow local users to access PostgreSQL without requiring a password, ensure the file `pg_hba.conf`, usually located in `/var/lib/pgsql/data`, contains the following lines.

```
local all all trust
host all all 127.0.0.1/32 trust
host all all ::1/128 trust
```

**Note**

Please note it is also possible to run dCache with all PostgreSQL accounts requiring passwords. See the section called “Configuring Access to PostgreSQL” for more advice on the configuration of PostgreSQL.

Restarting PostgreSQL

If you have edited PostgreSQL configuration files, you *must* restart PostgreSQL for those changes to take effect. On many systems, this can be done with the following command:

```
[root] # /etc/init.d/postgresql restart
Stopping postgresql service: [  OK  ]
Starting postgresql service: [  OK  ]
```

Configuring Chimera

Chimera is a library providing a hierarchical name space with associated meta data. Where pools in dCache store the content of files, Chimera stores the names and meta data of those files. Chimera itself stores the data in a relational database. We will use PostgreSQL in this tutorial. The properties of Chimera are defined in `/usr/share/dcache/defaults/chimera.properties`. See Chapter 4, *Chimera* for more information.

Initialize the database

Create the Chimera user and database and add the Chimera-specific tables and stored procedures:

```
[root] # createdb -U postgres chimera
CREATE DATABASE
[root] # createuser -U postgres --no-superuser --no-createrole --createdb --pwprompt chimera
Enter password for new role:
Enter it again:
CREATE ROLE
You do not need to enter a password.
[root] # psql -U chimera chimera -f /usr/share/dcache/chimera/sql/create.sql
psql:/usr/share/dcache/chimera/sql/create.sql:23: NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "t_inodes_pkey" for table "t_inodes"
CREATE TABLE
psql:/usr/share/dcache/chimera/sql/create.sql:35: NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "t_dirs_pkey" for table "t_dirs"
CREATE TABLE
psql:/usr/share/dcache/chimera/sql/create.sql:45: NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "t_inodes_data_pkey" for table "t_inodes_data"
many more like this...
```

Insert 0 1
Creating users and databases for dCache

The dCache components will access the database server with the user srmdcache which can be created with the `createuser`: for example:

```
[root] # createuser -U postgres --no-superuser --no-createrole --createdb --pwprompt srmdcache
You do not need to enter a password
```

Several management components running on the head node as well as the SRM will use the database dcache for storing their state information:

```
[root] # createdb -U srmdcache dcache
```

There might be several of these on several hosts. Each is used by the dCache components running on the respective host.

Now the configuration of PostgreSQL is done.

Generating ssh-keys

In order to use the Admin Interface of dCache (see the section called “The Admin Interface”) you will need to generate ssh-keys.

```
[root] # ssh-keygen -b 768 -t rsa1 -f /etc/dcache/server_key -N ""
Generating public/private rsa1 key pair.
Your identification has been saved in /etc/dcache/server_key.
Your public key has been saved in /etc/dcache/server_key.pub.
```
Installing dCache

The key fingerprint is:

[root] # ssh-keygen -b 1024 -t rsa1 -f /etc/dcache/host_key -N ""
Generating public/private rsa1 key pair.
Your identification has been saved in /etc/dcache/host_key.
The key fingerprint is:
75:a4:2b:24:cc:75:ad:b7:bd:8b:dd:1e:96:3f:9d root@example.org

Now you can start dCache.

[root] # dcache start
Starting dCacheDomain done

So far, no configuration is done, so only one predefined domain is started.

Configuring dCache

Terminology

dCache consists of one or more **domains**. A domain in dCache is a Java Virtual Machine hosting one or more dCache **cells**. Each domain must have a name which is unique throughout the dCache instance and a cell must have a unique name within the domain hosting the cell.

A **service** is an abstraction used in the dCache configuration to describe atomic units to add to a domain. It is typically implemented through one or more cells. dCache keeps lists of the domains and the services that are to be run within these domains in the **layout files**. The layout file may contain domain- and service- specific configuration values. A **pool** is a cell providing physical data storage services.

Configuration files

In the setup of dCache, there are three main places for configuration files:

- /usr/share/dcache/defaults
- /etc/dcache/dcache.conf
- /etc/dcache/layouts

The folder /usr/share/dcache/defaults contains the default settings of the dCache. If one of the default configuration values needs to be changed, copy the default setting of this value from one of the files in /usr/share/dcache/defaults to the file /etc/dcache/dcache.conf, which initially is empty and update the value.

**Note**

In this first installation of dCache your dCache will not be connected to a tape system. Therefore please change the values for DefaultRetentionPolicy and DefaultAccessLatency in the file /etc/dcache/dcache.conf.

```
DefaultRetentionPolicy=REPLICA
DefaultAccessLatency=ONLINE
```

Layouts describe which domains to run on a host and which services to run in each domain. For the customized configuration of your dCache you will create a mylayout.conf file in /etc/dcache/layouts.
**Important**

Do not update configuration values in the files in the defaults folder, since changes to these files will be overwritten by updates.

As the files in `/usr/share/dcache/defaults/` do serve as succinct documentation for all available configuration parameters and their default values it is quite useful to have a look at them.

### Defining domains and services

Domains and services are defined in the layout files. Depending on your site, you may have requirements upon the doors that you want to configure and domains within which you want to organise them.

A domain must be defined if services are to run in that domain. Services will be started in the order in which they are defined.

Every domain is a Java Virtual Machine that can be started and stopped separately. You might want to define several domains for the different services depending on the necessity of restarting the services separately.

The layout files define which domains to start and which services to put in which domain. Configuration can be done per domain and per service.

A name in square brackets, *without* a forward-slash (/) defines a domain. A name in square brackets *with* a forward-slash defines a service that is to run in a domain. Lines starting with a hash-symbol (#) are comments and will be ignored by dCache.

There may be several layout files in the layout directory, but only one of them is read by dCache when starting up. By default it is the `single.conf`. If the dCache should be started with another layout file you will have to make this configuration in `/etc/dcache/dcache.conf`.

```
dcache.layout=mylayout
```

This entry in `/etc/dcache/dcache.conf` will instruct dCache to read the layout file `/etc/dcache/layouts/mylayout.conf` when starting up.

These are the first lines of `/etc/dcache/layouts/single.conf`:

```
broker.scheme=none
[dCacheDomain]
[dCacheDomain/admin]
[dCacheDomain/broadcast]
[dCacheDomain/poolmanager]
```

[dCacheDomain] defines a domain called dCacheDomain. In this example only one domain is defined. All the services are running in that domain. Therefore no messagebroker is needed, which is the meaning of the entry `messageBroker=none`.

[dCacheDomain/admin] declares that the admin service is to be run in the dCacheDomain domain.

Here is an example for the first lines of the `mylayout.conf` of a single node dCache with several domains:

```
[dCacheDomain]
```

Installing dCache

---

**Important**

Having defined more than one domain, a messagebroker is needed. This is because the defined domains need to be able to communicate with each other. The default value is `messageBroker=cells`, as defined in the defaults `/usr/share/dcache/defaults/dcache.properties`.

**Creating and configuring pools**

dCache will need to write the files it keeps in pools. These pools are defined as services within dCache. Hence, they are added to the layout file of your dCache instance, like all other services.

The best way to create a pool, is to use the `dcache` script and restart the domain the pool runs in. The pool will be added to your layout file.

```
[domainname/pool]
name=poolname
path=/path/to/pool
waitForFiles=${path}/data
```

The property `waitForFiles` instructs the pool not to start up until the specified file or directory is available. This prevents problems should the underlying storage be unavailable (e.g., if a RAID device is offline).

**Note**

Please restart dCache if your pool is created in a domain that did not exist before.

```
[root] # dcache pool create /srv/dcache/p1 pool1 poolDomain
Created a pool in /srv/dcache/p1. The pool was added to poolDomain in file:/etc/dcache/layouts/mylayout.conf.
```

In this example we create a pool called pool1 in the directory `/srv/dcache/p1`. The created pool will be running in the domain poolDomain.

Now you need to change the ownership of the directories where your data is to be stored to the user running dCache which by default is dcache.

```
[root] # chown -R dcache /srv/dcache/p1
```
Installing dCache

Mind the Gap!

The default gap for poolsizes is 4GiB. This means you should make a bigger pool than 4GiB otherwise you would have to change this gap in the dCache admin tool. See the example below. See also the section called “The Admin Interface”.

```
(local) admin > cd poolname
(poolname) admin > set gap 2G
(poolname) admin > save
```

Adding a pool to a configuration does not modify the pool or the data in it and can thus safely be undone or repeated.

Java heap size

By default the Java heap size and the maximum direct buffer size are defined as

```
dcache.java.memory.heap=512m
dcache.java.memory.direct=512m
```

Again, these values can be changed in /etc/dcache/dcache.conf.

For optimization of your dCache you can define the Java heap size in the layout file separately for every domain.

```
[dCacheDomain]
dcache.java.memory.heap=2048m
dcache.java.memory.direct=0m
...
[utilityDomain]
dcache.java.memory.heap=384m
dcache.java.memory.direct=16m
```

Note

dCache uses Java to parse the configuration files and will search for Java on the system path first; if it is found there, no further action is needed. If Java is not on the system path, the environment variable JAVA_HOME defines the location of the Java installation directory. Alternatively, the environment variable JAVA can be used to point to the Java executable directly.

If JAVA_HOME or JAVA cannot be defined as global environment variables in the operating system, then they can be defined in either /etc/default/dcache or /etc/dcache.env. These two files are sourced by the init script and allow JAVA_HOME, JAVA and DCACHE_HOME to be defined.

Starting dCache

All configured components can now be started with dcache start.

```
[root] # dcache start
Starting dCacheDomain  Done (pid=7574)
Starting namespaceDomain  Done (pid=7647)
Starting gPlazmaDomain  Done (pid=8002)
Starting srmDomain  Done (pid=8081)
```
Now you can have a look at your dCache via The Web Interface, see the section called “The Web Interface for Monitoring dCache”: http://httpd.example.org:2288/, where httpd.example.org is the node on which your httpd service is running. For a single node dCache this is the machine on which your dCache is running.

Running dCache as a non-root user

For security reasons you might want to run dCache as a non-root user. This needs to be configured in /etc/dcache/dcache.conf and the ownership of the pools and the billing directories need to be changed.

In this example we explain how to configure dCache to run as user dcache.

First of all create the user dcache and a new directory /var/log/dcache, owned by dcache

```
[root] # useradd dcache
[root] # mkdir /var/log/dcache
[root] # chown dcache /var/log/dcache
```

and add two lines to /etc/dcache/dcache.conf.

```
dcache.user=dcache
dcache.paths.billing=/var/log/dcache
```

Change the ownership of the files /etc/grid-security/hostcert.pem and /etc/grid-security/hostkey.pem

```
[root] # chown dcache /etc/grid-security/hostcert.pem
[root] # chown dcache /etc/grid-security/hostkey.pem
```

In the layout file /etc/dcache/layouts/mylayout.conf a pool was defined.

```
[${{host.name}Domain/pool}
 name=pool1
 path=/path/to/pool1
 maxDiskSpace=2T
```

Change the ownership of the directory of the pool.

```
[root] # chown -R dcache /path/to/pool1
```

Moreover, if dCache has been running as root the files /tmp/createDDL.jdbc and /tmp/dropDDL.jdbc need to be removed as they are owned by the user root.

```
[root] # rm -f /tmp/createDDL.jdbc /tmp/dropDDL.jdbc
```

Important

If you switched the portmap daemon off the domain in which the NFS server is running needs to be running as root. This needs to be set in the layout file.

```
[namespaceDomain]
dcache.user=root
[namespaceDomain/pnfsmanager]
```
Installing dCache

Installing dCache on several nodes

Installing dCache on several nodes is not much more complicated than installing it on a single node. Think about how dCache should be organised regarding services and domains. Then adapt the layout files, as described in the section called “Defining domains and services”, to the layout that you have in mind. The files /etc/dcache/layouts/head.conf and /etc/dcache/layouts/pool.conf contain examples for a dCache head-node and a dCache pool respectively.

**Important**

You must configure a domain called dCacheDomain but the other domain names can be chosen freely.

Please make sure that the domain names that you choose are unique. Having the same domain names in different layout files on different nodes may result in an error.

On any other nodes than the head node, the property broker.host has to be added to the file /etc/dcache/dcache.conf. broker.host should point to the host running your dCache broker. Usually that is the host containing the special domain dCacheDomain, because that domain acts implicitly as a broker.

**Tip**

On dCache nodes running only pool services you do not need to install PostgreSQL. If your current node hosts only these services, the installation of PostgreSQL can be skipped.

Upgrading a dCache Instance

**Important**

Always read the release notes carefully before upgrading!

Upgrading to bugfix releases within one supported branch (e.g. from 1.9.12-1 to 1.9.12-2) may be done by upgrading the packages with

```bash
[namespaceDomain/cleaner]
[namespaceDomain/acl]
[namespaceDomain/nfsv3]
```

Now you can start dCache as user dcache

```
[root] # dcache start
Starting dCacheDomain done
Starting namespaceDomain done
Starting gPlazmaDomain done
Starting srmDomain done
```

and verify that dCache is running as dcache and the NFS server is running as root.

```
[root] # dcache status
DOMAIN        STATUS  PID   USER
----------------------
dCacheDomain    running 11040 dcache
namespaceDomain running 11117 root
gPlazmaDomain   running 11125 dcache
srmDomain       running 11182 dcache
```
Now dCache needs to be started again.

Chapter 3. Getting in Touch with dCache

This section is a guide for exploring a newly installed dCache system. The confidence obtained by this exploration will prove very helpful when encountering problems in the running system. This forms the basis for the more detailed stuff in the later parts of this book. The starting point is a fresh installation according to the section called “Installing a dCache instance”.

Checking the Functionality

Reading and writing data to and from a dCache instance can be done with a number of protocols. After a standard installation, these protocols are dCap, GSIdCap, and GridFTP. In addition dCache comes with an implementation of the SRM protocol which negotiates the actual data transfer protocol.

dCache without mounted namespace

Create the root of the Chimera namespace and a world-writable directory by

```bash
[root] # /usr/bin/chimera-cli mkdir /data
[root] # /usr/bin/chimera-cli mkdir /data/world-writable
[root] # /usr/bin/chimera-cli chmod /data/world-writable 777
```

WebDAV

To use WebDAV you need to define a WebDAV service in your layout file. You can define this service in an extra domain, e.g. `[webdavDomain]` or add it to another domain.

```conf
[webdavDomain]
[webdavDomain/webdav]
webdavAnonymousAccess=FULL
```

to the file `/etc/dcache/layouts/mylayout.conf`.

Note

Depending on the client you might need to set `webdav.redirect.on-read=false` and/or `webdav.redirect.on-write=false`.

```conf
#  ---- Whether to redirect GET requests to a pool
# If true, WebDAV doors will respond with a 302 redirect pointing to
# a pool holding the file. This requires that a pool can accept
# incoming TCP connections and that the client follows the
# redirect. If false, data is relayed through the door. The door
# will establish a TCP connection to the pool.
# (one-of?true|false)webdav.redirect.on-read=true

#  ---- Whether to redirect PUT requests to a pool
# If true, WebDAV doors will respond with a 307 redirect pointing to
# a pool to which to upload the file. This requires that a pool can
# accept incoming TCP connections and that the client follows the
# redirect. If false, data is relayed through the door. The door
```
Getting in Touch with dCache

```bash
# will establish a TCP connection to the pool. Only clients that send
# a Expect: 100-Continue header will be redirected - other requests
# will always be proxied through the door.
# (one-of?true|false)webdav.redirect.on-write=true
```

Now you can start the WebDAV domain

```
[root] # dcache start webdavDomain
```

and access your files via `http://webdav-door.example.org:2880` with your browser.

You can connect the webdav server to your file manager and copy a file into your dCache.

To use `curl` to copy a file into your dCache you will need to set `webdav.redirect.on-write=false`.

Write the file `test.txt`

```
```

and read it

```
```

### Using dCache with a mounted filesystem

dCache can also be used with a mounted file system. Before mounting the name space you need to edit the `/etc/exports` file. Add the lines

```
/ localhost(rw)
data
```

stop the portmapper

```
[root] # /etc/init.d/portmap stop
Stopping portmap: portmap
```

and restart dCache.

```
[root] # dcache restart
```

Now you can mount Chimera.

```
[root] # mount localhost:/ /mnt
```

With the root of the namespace mounted you can establish wormhole files so dCap clients can discover the dCap doors.

```
[root] # mkdir /mnt/admin/etc/config/dCache
[root] # touch /mnt/admin/etc/config/dCache/dcache.conf
[root] # touch /mnt/admin/etc/config/dCache/`.fset` `.fset` `.fset` `(dcache.conf)` `(io)` `(on)` `'
[root] # echo "dcache.example.org:22125" > /mnt/admin/etc/config/dCache/dcache.conf
```
Create the directory in which the users are going to store their data and change to this directory.

```bash
[root] # mkdir -p /mnt/data
[root] # cd /mnt/data
```

dCap

to be able to use dCap you need to have the dCap door running in a domain.

```bash
[dCacheDomain]
[dCacheDomain/dcap]
```

For this tutorial install dCap on your worker node. This can be the machine where your dCache is running.

Get the gLite repository (which contains dCap) and install dCap using `yum`.

```bash
[root] # cd /etc/yum.repos.d/
[root] # yum install dcap
```

dCap without mounted namespace

Create the root of the Chimera namespace and a world-writable directory for dCap to write into by

```bash
[root] # /usr/bin/chimera-cli mkdir /data
[root] # /usr/bin/chimera-cli mkdir /data/world-writable
[root] # /usr/bin/chimera-cli chmod /data/world-writable 777
```

Copy the data (here `'/bin/sh'` is used as example data) using the `dccp` command and the dCap protocol describing the location of the file using a URL, where `dcache.example.org` is the host on which the dCache is running

```bash
[root] # dccp -H '/bin/sh' dcap://dcache.example.org/data/world-writable/my-test-file-1
#-------------------------------arnation] 100%
718 kb 735004 bytes (718 kb) in 0 seconds
and copy the file back.

```bash
[root] # dccp -H dcap://dcache.example.org/data/world-writable/my-test-file-1 /tmp/mytestfile1
#-------------------------------arnation] 100%
718 kb 735004 bytes (718 kb) in 0 seconds
```

To remove the file you will need to mount the namespace.

Using dCap with a mounted filesystem

dCap can also be used with a mounted file system. Before mounting the name space you need to edit the `/etc/exports` file. Add the lines

```bash
/ localhost(rw)
```
Getting in Touch with dCache

stop the portmapper

```
[root] # /etc/init.d/portmap stop
Stopping portmap: portmap
```

and restart dCache.

```
[root] # dcache restart
```

Now you can mount Chimera.

```
[root] # mount localhost:/ /mnt
```

With the root of the namespace mounted you can establish wormhole files so dCap clients can discover the dCap doors.

```
[root] # mkdir /mnt/admin/etc/config/dCache
[root] # touch /mnt/admin/etc/config/dCache/`{fset}`(dcache.conf)`{io}`(on)`
[root] # echo "dcache.example.org:22125" > /mnt/admin/etc/config/dCache/dcache.conf
```

Create the directory in which the users are going to store their data and change to this directory.

```
[root] # mkdir -p /mnt/data
[root] # cd /mnt/data
```

Now you can copy a file into your dCache

```
[root] # dccp /bin/sh my-test-file-2
735004 bytes (718 kiB) in 0 seconds
```

and copy the data back using the `dccp` command.

```
[root] # dccp my-test-file-2 /tmp/mytestfile2
735004 bytes (718 kiB) in 0 seconds
```

The file has been transferred successfully.

Now remove the file from the dCache.

```
[root] # rm my-test-file-2
```

**Authentication and Authorization in dCache**

In dCache digital certificates are used for authentication and authorisation. To be able to verify the chain of trust when using the non-commercial grid-certificates you should install the list of certificates of grid Certification Authorities (CAs). In case you are using commercial certificates you will find the list of CAs in your browser.
You will need a server certificate for the host on which your dCache is running and a user certificate. The host certificate needs to be copied to the directory `/etc/grid-security/` on your server and converted to `hostcert.pem` and `hostkey.pem` as described in Using X.509 Certificates. Your user certificate is usually located in `.globus`. If it is not there you should copy it from your browser to `.globus` and convert the `*.p12` file to `usercert.pem` and `userkey.pem`.

If you have the clients installed on the machine on which your dCache is running you will need to add a user to that machine in order to be able to execute the `voms-proxy-init` command and execute `voms-proxy-init` as this user.

```
[root] # useradd johndoe
```

Change the password of the new user in order to be able to copy files to this account.

```
[root] # passwd johndoe
Changing password for user johndoe.
New UNIX password: 
Retype new UNIX password: 
passwd: all authentication tokens updated successfully.
[root] # su johndoe
[user] $ cd
[user] $ mkdir .globus
```

Copy your key files from your local machine to the new user on the machine where the dCache is running.

```
[user] $ scp .globus/user*.pem johndoe@dcache.example.org: .globus
```

Install glite-security-voms-clients (contained in the gLite-UI).

```
[root] # yum install glite-security-voms-clients
```

Generate a proxy certificate using the command `voms-proxy-init`.

```
[user] $ voms-proxy-init
Enter GRID pass phrase: 
Your identity: /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
Creating proxy .............................................. Done
```
Getting in Touch with dCache

Your proxy is valid until Mon Mar  7 22:06:15 2011

With `voms-proxy-init -voms yourVO` you can add VOMS attributes to the proxy. A user’s roles (Fully Qualified Attribute Names) are read from the certificate chain found within the proxy. These attributes are signed by the user’s VOMS server when the proxy is created. For the `voms-proxy-init -voms` command you need to have the file `/etc/vomses` which contains entries about the VOMS servers like

```
"desy" "grid-voms.desy.de" "15104" "/C=DE/O=GermanGrid/CN=host/grid-voms.desy.de" "desy" "24"
"atlas" "voms.cern.ch" "15001" "/DC=ch/DC=cern/OU=computers/CN=voms.cern.ch" "atlas" "24"
"dteam" "lcg-voms.cern.ch" "15004" "/DC=ch/DC=cern/OU=computers/CN=lcg-voms.cern.ch" "dteam" "24"
"dteam" "voms.cern.ch" "15004" "/DC=ch/DC=cern/OU=computers/CN=voms.cern.ch" "dteam" "24"
```

Now you can generate your voms proxy containing your VO.

```
[user]$ voms-proxy-init -voms desy
Enter GRID pass phrase:
Your identity: /C=DE/O=GermanGrid/CN=John Doe
Creating temporary proxy ................................... Done
Contacting  grid-voms.desy.de:15104 [/C=DE/O=GermanGrid/CN=host/grid-voms.desy.de] "desy" Done
Creating proxy .................... Done
Your proxy is valid until Thu Mar 31 21:49:06 2011
```

Authentication and authorization in dCache is done by the gplazma service. Define this service in the layout file.

```
[gPlazmaDomain]
[gPlazmaDomain/gplazma]
```

In this tutorial we will use the gplazmalite-vorole-mapping plugin. To this end you need to edit the `/etc/grid-security/grid-vorolemap` and the `/etc/grid-security/storage-authzdb` as well as the `/etc/dcache/dcachesrm-gplazma.policy`.

The `/etc/grid-security/grid-vorolemap`:

```
"/C=DE/O=GermanGrid/O=DESY/CN=John Doe" "/desy" doegroup
```

The `/etc/grid-security/storage-authzdb`:

```
version 2.1
authorize doegroup read-write 12345 1234 / / 
```

The `/etc/dcache/dcachesrm-gplazma.policy`:

```
# Switches
xacml-vo-mapping="OFF"
saml-vo-mapping="OFF"
kpwd="OFF"
gridsmapfile="OFF"
gplazmalite-vorole-mapping="ON"

# Priorities
xacml-vo-mapping-priority="5"
saml-vo-mapping-priority="2"
kpwd-priority="3"
gridsmapfile-priority="4"
gplazmalite-vorole-mapping-priority="1"
```
How to work with secured dCache

If you want to copy files into dCache with GSIdCap, SRM or WebDAV with certificates you need to follow the instructions in the section above.

**GSIdCap**

To use GSIdCap you must run a GSIdCap door. This is achieved by including the gsidcap service in your layout file on the machine you wish to host the door.

```
[gsidcapDomain]
[gsidcapDomain/gsidcap]
```

In addition, you need to have libdcap-tunnel-gsi installed on your worker node, which is contained in the gLite-UI.

**Note**

As ScientificLinux 5 32bit is not supported by gLite there is no libdcap-tunnel-gsi for SL5 32bit.

```
[root] # yum install libdcap-tunnel-gsi
```

It is also available on the dCap downloads page [http://www.dcache.org/downloads/dcap/].

```
[root] # rpm -i http://www.dcache.org/repository/yum/sl5/x86_64/RPMS.stable/libdcap-tunnel-gsi-2.47.5-0.x86_64.rpm
```

The machine running the GSIdCap door needs to have a host certificate and you need to have a valid user certificate. In addition, you should have created a voms proxy as mentioned above.

Now you can copy a file into your dCache using GSIdCap

```
[user] $ dcp /bin/sh gsidcap://dcache.example.org:22128/data/world-writable/my-test-file3
801512 bytes in 0 seconds
```

and copy it back

```
801512 bytes in 0 seconds
```

**SRM**

To use the SRM you need to define the srm service in your layout file.

```
[srmDomain]
[srmDomain/srm]
```

In addition, the user needs to install an SRM client for example the dcache-srmclient, which is contained in the gLite-UI, on the worker node and set the PATH environment variable.
Getting in Touch with dCache

You can now copy a file into your dCache using the SRM,

```
[user] $ srmcp -2 file:///bin/sh srm://dcache.example.org:8443/data/world-writable/my-test-file4
```

copy it back

```
[user] $ srmcp -2 srm://dcache.example.org:8443/data/world-writable/my-test-file4 file:///tmp/mytestfile4.tmp
```

and delete it

```
[user] $ srmrm -2 srm://dcache.example.org:8443/data/world-writable/my-test-file4
```

If the grid functionality is not required the file can be deleted with the NFS mount of the Chimera namespace:

```
[user] $ rm /data/world-writable/my-test-file4
```

**WebDAV with certificates**

To use WebDAV with certificates you change the entry in `/etc/dcache/lay-outs/mylayout.conf` from

```
[webdavDomain]
[webdavDomain/webdav]
webdavAnonymousAccess=FULL
webdavRootPath=/data/world-writable
```

to

```
[webdavDomain]
[webdavDomain/webdav]
webdavAnonymousAccess=NONE
webdavRootPath=/data/world-writable
webdavProtocol=https
```

Then you will need to import the host certificate into the dCache keystore using the command

```
[root] # dcache import hostcert
```

and initialise your truststore by

```
[root] # dcache import cacerts
```

Now you need to restart the WebDAV domain

```
[root] # dcache restart webdavDomain
```

and access your files via `https://dcache.example.org:2880` with your browser.
Important

If the host certificate contains an extended key usage extension, it must include the extended usage for server authentication. Therefore you have to make sure that your host certificate is either unrestricted or it is explicitly allowed as a certificate for TLS Web Server Authentication.

Allowing authenticated and non-authenticated access with WebDAV

You can also choose to have secure and insecure access to your files at the same time. You might for example allow access without authentication for reading and access with authentication for reading and writing.

```plaintext
[webdavDomain]
[webdavDomain/webdav]
webdavRootPath=/data/world-writable
webdavAnonymousAccess=READONLY
port=2880
webdavProtocol=https
```

You can access your files via https://dcache.example.org:2880 with your browser.

The Web Interface for Monitoring dCache

In the standard configuration the dCache web interface is started on the head node (meaning that the domain hosting the httpd service is running on the head node) and can be reached via port 2288. Point a web browser to http://head-node.example.org:2288/ to get to the main menu of the dCache web interface. The contents of the web interface are self-explanatory and are the primary source for most monitoring and trouble-shooting tasks.

The “Cell Services” page displays the status of some important cells of the dCache instance.

The “Pool Usage” page gives a good overview of the current space usage of the whole dCache instance. In the graphs, free space is marked yellow, space occupied by cached files (which may be deleted when space is needed) is marked green, and space occupied by precious files, which cannot be deleted is marked red. Other states (e.g., files which are currently written) are marked purple.

The page “Pool Request Queues” (or “Pool Transfer Queues”) gives information about the number of current requests handled by each pool. “Actions Log” keeps track of all the transfers performed by the pools up to now.

The remaining pages are only relevant with more advanced configurations: The page “Pools” (or “Pool Attraction Configuration”) can be used to analyze the current configuration of the pool selection unit in the pool manager. The remaining pages are relevant only if a tertiary storage system (HSM) is connected to the dCache instance.

Files

In this section we will have a look at the configuration and log files of dCache.

The dCache software is installed in various directories according to the Filesystem Hierarchy Standard. All configuration files can be found in /etc/dcache.
In the previous section we have already seen how a domain is restarted:

```
[root] # dcache restart domainName
```

Log files of domains are by default stored in `/var/log/dcache/domainName.log`. We strongly encourage to configure logrotate to rotate the dCache log files to avoid filling up the log file system. This can typically be achieved by creating the file `/etc/logrotate.d/dcache` with the following content:

```
/var/log/dcache/*.log {
    compress
    rotate 100
    missingok
    copytruncate
}
```

More details about domains and cells can be found in Chapter 6, *The Cell Package*.

The most central component of a dCache instance is the PoolManager cell. It reads additional configuration information from the file `/var/lib/dcache/config/poolmanager.conf` at start-up. However, it is not necessary to restart the domain when changing the file. We will see an example of this below.

Similar to `/var/lib/dcache/config/poolmanager.conf`, pools read their configuration from `poolDir/pool/setup` at startup.

**The Admin Interface**

*Just use commands that are documented here*

Only commands described in this documentation should be used for the administration of a dCache system.

**First steps**

*Note*

If you attempt to log into the admin interface without generating the `ssh`-keys you will get an error message.

```
[user] $ ssh -c blowfish -p 22223 -l admin headnode.example.org
Connection closed by 192.0.2.11
```

See the section called “Generating `ssh`-keys”.

dCache has a powerful administration interface. It is accessed with the `ssh` protocol. The server is part of the `adminDoor` domain. Connect to it with

```
[user] $ ssh -c blowfish -p 22223 -l admin headnode.example.org
```

The initial password is “dickerelch” (which is German for “fat elk”) and you will be greeted by the prompt
The password can now be changed with

```
(local) admin > cd acm
(acm) admin > create user admin
(acm) admin > set passwd -user=admin newPasswd newPasswd
(local) admin > ..
```

This already illustrates how to navigate within the administration interface:

Starting from the local prompt (`(local) admin >`) the command `cd` takes you to the specified cell (here `acm`, the access control manager). There two commands are executed. The escape sequence `..` takes you back to the local prompt and `logoff` exits the admin shell.

There also is the command `help` for listing all commands the cell knows and their parameters. However, many of the commands are only used for debugging and development purposes.

**Note**

If the cells are well-known, they can be accessed without adding the domain-scope. See Chapter 6, *The Cell Package* for more information.

The domains that are running on the dCache-instance, can be viewed in the layout-configuration (see Chapter 2, *Installing dCache*). Additionally, there is the `topo` cell, which keeps track of the instance’s domain topology. If it is running, it can be used to obtain the list of domains the following way:

```
(local) admin > cd topo
(topo) admin > ls
adminDoorDomain
gsidcapDomain
dcapDomain
utilityDomain
gPlazmaDomain
webdavDomain
gridftpDomain
srmdomain
dCacheDomain
httpdDomain
namespaceDomain
poolDomain
```

**Note**

The `topo` cell rescans periodically which domains are running, so it can take some time until `ls` displays the full domain list.

If you want to find out which cells are running on a certain domain, you can issue the command `ps` in the `System` cell of the domain.

For example, if you want to list the cells running on the `poolDomain`, `cd` to its `System` cell and issue the `ps` command.

```
(topo) admin > ..
(local) admin > cd System@poolDomain
```
Getting in Touch with dCache

The cells in the domain can be accessed using `cd` together with the cell-name scoped by the domain-name. So first, one has to get back to the local prompt, as the `cd` command will not work otherwise.

**Note**

Note that `cd` only works from the local prompt. If the cell you are trying to access does not exist, the `cd` command will complain.

```
(local) admin > cd nonsense
java.lang.IllegalArgumentException: Cannot cd to this cell as it doesn't exist
```

Type `..` to return to the (local) `admin >` prompt.

Login to the routing manager of the `dCacheDomain` to get a list of all well-known cells you can directly `cd` to without having to add the domain.

```
(System@poolDomain) admin > ..
(local) admin > cd RoutingMgr@dCacheDomain
(RoutingMgr@dCacheDoorDomain) admin > ls
Our routing knowledge :
Local : [PoolManager, topo, broadcast, LoginBroker, info]
adminDoorDomain : [pam]
gsidcapDomain : [Dcap-gsi-example.dcache.org]
dcapDomain : [Dcap-example.dcache.org]
utilityDomain : [gsi-pam, PinManager]
gPlazmaDomain : [gPlazma]
webdavDomain : [WebDAV-example.dcache.org]
gsiftpDomain : [GSIFTP-example.dcache.org]
srmDomain : [RemoteTransferManager, CopyManager, SrmSpaceManager, SRM-example.dcache.org]
httpdDomain : [billing, srm-LoginBroker, TransferObserver]
poolDomain : [pool_2, pool_1]
namespaceDomain : [PnfsManager, dirLookupPool, cleaner]
```

All cells know the commands `info` for general information about the cell and `show pinboard` for listing the last lines of the `pinboard` of the cell. The output of these commands contains useful information for solving problems.

It is a good idea to get acquainted with the normal output in the following cells: `PoolManager`, `PnfsManager`, and the pool cells (e.g., `poolHostname_1`).

The most useful command of the pool cells is `rep ls`. To execute this command `cd` into the pool. It lists the files which are stored in the pool by their `pnfs` IDs:

```
(RoutingMgr@dCacheDoorDomain) admin > ..
(pool_1) admin > rep ls
000100000000000000001120 <-P---------(0)[0]> 485212 si={myStore:STRING}
000100000000000000001230 <-C----------(0)[0]> 1222287360 si={myStore:STRING}
```

Each file in a pool has one of the 4 primary states: “cached” (`<C--->`), “precious” (`<-P--->`), “from client” (`<--C-`), and “from store” (`<---S`).
Getting in Touch with dCache

See the section called “How to Store-/Restore files via the Admin Interface” for more information about `rep ls`.

The most important commands in the **PoolManager** are: `rc ls` and `cm ls -r`.

`rc ls` lists the requests currently handled by the PoolManager. A typical line of output for a read request with an error condition is (all in one line):

```
(pool_1) admin > ..
(local) admin > cd PoolManager
(PoolManager) admin > rc ls
000100000000000000001230@0.0.0.0/0.0.0.0 m=1 r=1 [unknown]
[Waiting 08.28 19:14:16]
(149, No pool candidates available or configured for 'staging')
```

As the error message at the end of the line indicates, no pool was found containing the file and no pool could be used for staging the file from a tertiary storage system.

See the section called “Obtain information via the dCache Command Line Admin Interface” for more information about the command `rc ls`.

Finally, `cm ls` with the option `-r` gives the information about the pools currently stored in the cost module of the pool manager. A typical output is:

```
(PoolManager) admin > cm ls -r
pool_1={R={a=0;m=2;q=0};S={a=0;m=2;q=0};M={a=0;m=100;q=0};PS={a=0;m=20;q=0};PC={a=0;m=20;q=0};
(...continues...) SP={t=2147483648;f=924711076;p=1222772572;r=0;1ru=0;[q=20000000;be=0.5])
pool_1={Tag={{hostname=example.org}};size=0;SC=0.16221282938326134;CC=0.0;}
pool_2={R={a=0;m=2;q=0};S={a=0;m=2;q=0};M={a=0;m=100;q=0};PS={a=0;m=20;q=0};PC={a=0;m=20;q=0};
(...continues...) SP={t=2147483648;f=2147483648;p=0;r=0;1ru=0;[q=4294967296;b=250.0;]}
pool_2={Tag={{hostname=example.org}};size=0;SC=2.7939677238464355E-4;CC=0.0;}
```

While the first line for each pool gives the information stored in the cache of the cost module, the second line gives the costs (SC: space cost, CC: performance cost) calculated for a (hypothetical) file of zero size. For details on how these are calculated and their meaning, see the section called “The Cost Module”.

### Create a new user

To create a new user, `new-user` and set a new password for the user `cd` from the local prompt (`(local) admin >`) to the `acm`, the access control manager, and run following command sequence:

```
(local) admin > cd acm
(acm) admin > create user new-user
(acm) admin > set passwd -user=new-user newPasswd newPasswd
```

For the new created users there will be an entry in the directory `/etc/dcache/admin/users/meta`.

**Note**

As the initial user `admin` has not been created with the above command you will not find him in the directory `/etc/dcache/admin/users/meta`.

Give the new user access to a particular cell:

```
(acm) admin > create acl cellName.execute
```
Getting in Touch with dCache

Give the new user access to the PnfsManager.

```text
(acm) admin > add access -allowed cell.cellName.execute new-user
```

Now you can check the permissions by:

```text
(acm) admin > create acl cell.PnfsManager.execute
(acm) admin > add access -allowed cell.PnfsManager.execute new-user
```

The following commands allow access to every cell for a user `new-user`:

```text
(acm) admin > create acl cell.*.execute
(acm) admin > add access -allowed cell.*.execute new-user
```

The following command makes a user as powerful as `admin` (dCache’s equivalent to the `root` user):

```text
(acm) admin > create acl *.*.*
(acm) admin > add access -allowed *.*.* new-user
```

### Use of the ssh Admin Interface by scripts

The ssh admin interface can be used non-interactively by scripts. For this the dCache-internal ssh server uses public/private key pairs.

The file `/etc/dcache/authorized_keys` contains one line per user. The file has the same format as `~/.ssh/authorized_keys` which is used by `sshd`. The keys in `/etc/dcache/authorized_keys` have to be of type RSA1 as dCache only supports SSH protocol 1. Such a key is generated with

```bash
[user] $ ssh-keygen -t rsa1 -C 'SSH1 key of user'
Generating public/private rsa1 key pair.
Enter file in which to save the key (/home/user/.ssh/identity):
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/user/.ssh/identity.
Your public key has been saved in /home/user/.ssh/identity.pub.
The key fingerprint is:
```

The passphrase is used to encrypt the private key (now stored in `/home/user/.ssh/identity`). If you do not want to enter the passphrase every time the private key is used, you can use `ssh-add` to add it to a running `ssh-agent`. If no agent is running start it with

```bash
[user] $ if [ -S $SSH_AUTH_SOCK ]; then echo "Already running" ; else eval `ssh-agent` ; fi
```

and add the key to it with

```bash
[user] $ ssh-add
Enter passphrase for SSH1 key of user:
Identity added: /home/user/.ssh/identity (SSH1 key of user)
```
Now, insert the public key `~/.ssh/identity.pub` as a separate line into `/etc/dcache/authorized_keys`. The comment field in this line “SSH1 key of user” has to be changed to the dCache user name. An example file is:

```
1024 35 141939124(... many more numbers ...)15331 admin
```

Using `ssh-add -L >> /etc/dcache/authorized_keys` will not work, because the line added is not correct. The key manager within dCache will read this file every minute.

Now, the `ssh` program should not ask for a password anymore. This is still quite secure, since the unencrypted private key is only held in the memory of the `ssh-agent`. It can be removed from it with

```
[user] $ ssh-add -d
Identity removed: /home/user/.ssh/identity (RSA1 key of user)
```

In scripts, one can use a “Here Document” to list the commands, or supply them to `ssh` as standard-input (stdin). The following demonstrates using a Here Document:

```
#!/bin/sh
#
# Script to automate dCache administrative activity
outfile=/tmp/$(basename $0).$$.$$.out
ssh -c blowfish -p 22223 admin@adminNode > $outfile << EOF
cd PoolManager
cm ls -r
(more commands here)
logoff
EOF
```

or, the equivalent as stdin.

```
#!/bin/bash
#
# Script to automate dCache administrative activity.
echo -e 'cd pool_1
rep ls
(more commands here)
logoff'
| ssh -c blowfish -p 22223 admin@adminNode
| tr -d '\r' > rep_ls.out
```

This part contains descriptions of the components of dCache, their role, functionality within the framework. In short, all information necessary for configuring them.
Chapter 4. Chimera

dCache is a distributed storage system, nevertheless it provides a single-rooted file system view. While dCache supports multiple namespace providers, Chimera is the recommended provider and is used by default.

The inner dCache components talk to the namespace via a module called PnfsManager, which in turn communicates with the Chimera database using a thin Java layer, which in turn communicates directly with the Chimera database. Chimera allows direct access to the namespace by providing an NFSv3 and NFSv4.1 server. Clients can NFS-mount the namespace locally. This offers the opportunity to use OS-level tools like ls, mkdir, mv for Chimera. Direct I/O-operations like cp and cat are possible with the NFSv4.1 door.

The properties of Chimera are defined in /usr/share/dcache/defaults/chimera.properties. For customisation the files /etc/dcache/layouts/mylayout.conf or /etc/dcache/dcache.conf should be modified (see the section called “Defining domains and services”).

This example shows an extract of the /etc/dcache/layouts/mylayout.conf file in order to run dCache with NFSv3.

```conf
[namespaceDomain]
[namespaceDomain/pnfsmanager]
[namespaceDomain/nfsv3]
```

If you want to run the NFSv4.1 server you need to add the corresponding nfsv41 service to a domain in the /etc/dcache/layouts/mylayout.conf file and start this domain.

```conf
[namespaceDomain]
[namespaceDomain/pnfsmanager]
[namespaceDomain/nfsv41]
```

If you wish dCache to access your Chimera with a PostgreSQL user other than chimera then you must specify the username and password in /etc/dcache/dcache.conf.

```conf
chimera.db.user=myuser
chimera.db.password=secret
```

Important

Do not update configuration values in /usr/share/dcache/defaults/chimera.properties, since changes to this file will be overwritten by updates.

Mounting Chimera through NFS

dCache does not need the Chimera filesystem to be mounted but a mounted file system is convenient for administrative access. This offers the opportunity to use OS-level tools like ls and mkdir for Chimera. However, direct I/O-operations like cp are not possible, since the NFSv3 interface provides the namespace part only. This section describes how to start the Chimera NFSv3 server and mount the name space.

If you want to mount Chimera for easier administrative access, you need to edit the /etc/exports file as the Chimera NFS server uses it to manage exports. If this file doesn’t exist it must be created. The typical exports file looks like this:
As any RPC service Chimera NFS requires the rpcbind service to run on the host. Nevertheless rpcbind has to be configured to accept requests from Chimera NFS.

On RHEL6 based systems you need to add

```
RPCBIND_ARGS="--i"
```

into `/etc/sysconfig/rpcbind` and restart rpcbind. Check your OS manual for details.

```
[root] # service rpcbind restart
Stopping rpcbind: [ OK ]
Starting rpcbind:  [ OK ]
```

If your OS does not provide rpcbind Chimera NFS can use an embedded rpcbind. This requires to disable the portmap service if it exists.

```
[root] # /etc/init.d/portmap stop
Stopping portmap: portmap
```

and restart the domain in which the NFS server is running.

```
[root] # dcache restart namespaceDomain
```

Now you can mount Chimera by

```
[root] # mount localhost:/ /mnt
```

and create the root of the Chimera namespace which you can call `data`:

```
[root] # mkdir -p /mnt/data
```

If you don’t want to mount chimera you can create the root of the Chimera namespace by

```
[root] # /usr/bin/chimera-cli Mkdir /data
```

You can now add directory tags. For more information on tags see the section called “Directory Tags”.

```
[root] # echo "chimera" | /usr/bin/chimera-cli Writetag /data sGroup
[root] # echo "StoreName sql" | /usr/bin/chimera-cli Writetag /data OSMTemplate
```

**Using dCap with a mounted file system**

If you plan to use dCap with a mounted file system instead of the URL-syntax (e.g. `ddeep /data/file1 /tmp/file1`), you need to mount the root of Chimera locally (remote mounts are not allowed yet). This will allow us to establish wormhole files so dCap clients can discover the dCap doors.

```
[root] # mount localhost:/ /mnt
```
The default values for ports can be found in Chapter 29, *dCache Default Port Values* (for dCap the default port is 22125) and in the file `/usr/share/dcache/defaults/dcache.properties`. They can be altered in `/etc/dcache/dcache.conf`.

When the configuration is complete you can unmount Chimera:

```
[root] # umount /mnt
```

**Note**

Please note that whenever you need to change the configuration, you have to remount the root `localhost:/` to a temporary location like `/mnt`.

## Communicating with Chimera

Many configuration parameters of Chimera and the application specific meta data is accessed by reading, writing, or creating files of the form `.(command)para`. For example, the following prints the ChimeraID of the file `/data/some/dir/file.dat`:

```
[user] $ cat /data/any/sub/directory/.(id)(file.dat)
0004000000000000002320B8 [user] $
```

From the point of view of the NFS protocol, the file `.id(file.dat)` in the directory `/data/some/dir/` is read. However, Chimera interprets it as the command `id` with the parameter `file.dat` executed in the directory `/data/some/dir/`. The quotes are important, because the shell would otherwise try to interpret the parentheses.

Some of these command files have a second parameter in a third pair of parentheses. Note, that files of the form `.command(para)` are not really files. They are not shown when listing directories with `ls`. However, the command files are listed when they appear in the argument list of `ls` as in

```
[user] $ ls -l .(tag)(sGroup)
-rw-r--r-- 11 root root 7 Aug 6 2010 .(tag)(sGroup)
```

Only a subset of file operations are allowed on these special command files. Any other operation will result in an appropriate error. Beware, that files with names of this form might accidentally be created by typos. They will then be shown when listing the directory.

### IDs

Each file in Chimera has a unique 18 byte long ID. It is referred to as ChimeraID or as pnfsID. This is comparable to the inode number in other filesystems. The ID used for a file will never be reused, even if the file is deleted. dCache uses the ID for all internal references to a file.

The ID of the file `example.org/data/examplefile` can be obtained by reading the command-file `.id(examplefile)` in the directory of the file.

```
[user] $ cat /example.org/data/./(id)(examplefile)
```
A file in Chimera can be referred to by the ID for most operations.

The name of a file can be obtained from the ID with the command `nameof` as follows:

```
[user]$ cd /example.org/data/
[user]$ cat `.nameof)(0000917F4A82369F4BA98E38DBC5687A031D)`
examplefile
```

And the ID of the directory it resides in is obtained by:

```
[user]$ cat `.parent)(0000917F4A82369F4BA98E38DBC5687A031D)`
0000595ABA40B31A469C87754CD79E0C08F2
```

This way, the complete path of a file may be obtained starting from the ID.

**Directory Tags**

In the Chimera namespace, each directory can have a number of tags. These directory tags may be used within dCache to control the file placement policy in the pools (see the section called “The Pool Selection Mechanism”). They might also be used by a tertiary storage system for similar purposes (e.g. controlling the set of tapes used for the files in the directory).

**Note**

Directory tags are not needed to control the behaviour of dCache. dCache works well without directory tags.

**Create, List and Read Directory Tags if the Namespace is not Mounted**

You can create tags with

```
[user]$ echo "content" | /usr/bin/chimera-cli writetag directory tagName
```

list tags with

```
[user]$ /usr/bin/chimera-cli lstag directory
```

and read tags with

```
[user]$ /usr/bin/chimera-cli readtag directory tagName
```

Create tags for the directory `data` with

```
[user]$ echo "myGroup" | /usr/bin/chimera-cli writetag /data sGroup
[user]$ echo "StoreName myStore" | /usr/bin/chimera-cli writetag /data OSMTemplate
```

list the existing tags with

```
[user]$ /usr/bin/chimera-cli lstag /data
```
and their content with

```
[user] $ /usr/bin/chimera-cli readtag /data OSMTemplate
StoreName myStore
[user] $ /usr/bin/chimera-cli readtag /data sGroup
myGroup
```

### Create, List and Read Directory Tags if the Namespace is Mounted

If the namespace is mounted, change to the directory for which the tag should be set and create a tag with

```
[user] $ cd directory
[user] $ echo 'content1' > '.(tag)(tagName1)'
[user] $ echo 'content2' > '.(tag)(tagName2)'
```

Then the existing tags may be listed with

```
[user] $ cat '.(tags)()' 
.(tag)(tagname1) 
.(tag)(tagname2)
```

and the content of a tag can be read with

```
[user] $ cat '.(tag)(tagname1)'
content1
[user] $ cat '.(tag)(tagName2)'
content2
```

Create tags for the directory data with

```
[user] $ cd data
[user] $ echo 'StoreName myStore' > '.(tag)(OSMTemplate)'
[user] $ echo 'myGroup' > '.(tag)(sGroup)'
```

list the existing tags with

```
[user] $ cat '.(tags)()' 
.(tag)(OSMTemplate) 
.(tag)(sGroup)
```

and their content with

```
[user] $ cat '.(tag)(OSMTemplate)'
StoreName myStore
[user] $ cat '.(tag)(sGroup)'
myGroup
```

A nice trick to list all tags with their contents is

```
[user] $ grep "" $(cat '.(tags)()')
.(tag)(OSMTemplate):StoreName myStore
```

35
Directory Tags and Command Files

When creating or changing directory tags by writing to the command file as in

```
[user] $ echo 'content' > '.(tag) (tagName)'
```

one has to take care not to treat the command files in the same way as regular files, because tags are different from files in the following aspects:

1. The `tagName` is limited to 62 characters and the `content` to 512 bytes. Writing more to the command file, will be silently ignored.

2. If a tag which does not exist in a directory is created by writing to it, it is called a primary tag.

3. Tags are inherited from the parent directory by a newly created directory. Changing a primary tag in one directory will change the tags inherited from it in the same way. Creating a new primary tag in a directory will not create an inherited tag in its subdirectories.

   Moving a directory within the Chimera namespace will not change the inheritance. Therefore, a directory does not necessarily inherit tags from its parent directory. Removing an inherited tag does not have any effect.

4. Empty tags are ignored.

Directory Tags for dCache

The following directory tags appear in the dCache context:

- **OSMTemplate**
  - Must contain a line of the form “StoreName storeName” and specifies the name of the store that is used by dCache to construct the storage class if the HSM Type is osm.

- **HSMType**
  - The HSMType tag is normally determined from the other existing tags. E.g., if the tag OSMTemplate exists, HSMType=osm is assumed. With this tag it can be set explicitly. A class implementing that HSM type has to exist. Currently the only implementations are osm and enstore.

- **sGroup**
  - The storage group is also used to construct the storage class if the HSMType is osm.

- **cacheClass**
  - The cache class is only used to control on which pools the files in a directory may be stored, while the storage class (constructed from the two above tags) might also be used by the HSM. The cache class is only needed if the above two tags are already fixed by HSM usage and more flexibility is needed.

- **hsmInstance**
  - If not set, the hsmInstance tag will be the same as the HSMType tag. Setting this tag will only change the name as used in the storage class and in the pool commands.

Storage Class and Directory Tags

The storage class is a string of the form `StoreName:StorageGroup@hsm-type`, where `StoreName` is given by the OSMTemplate tag, `StorageGroup` by the sGroup tag and `hsm-type` by
the HSMType tag. As mentioned above the HSMType tag is assumed to be osm if the tag OSMTemplate exists.

In the examples above two tags have been created.

```
[user] $ /usr/bin/chimera-cli lstag /data
Total: 2
OSMTemplate
sGroup
```

As the tag OSMTemplate was created the tag HSMType is assumed to be osm.

The storage class of the files which are copied into the directory /data after the tags have been set will be myStore:myGroup@osm.

If directory tags are used to control the behaviour of dCache and/or a tertiary storage system, it is a good idea to plan the directory structure in advance, thereby considering the necessary tags and how they should be set up. Moving directories should be done with great care or even not at all. Inherited tags can only be created by creating a new directory.

Assume that data of two experiments, experiment-a and experiment-b is written into a namespace tree with subdirectories /data/experiment-a and /data/experiment-b. As some pools of the dCache are financed by experiment-a and others by experiment-b they probably do not like it if they are also used by the other group. To avoid this the directories of experiment-a and experiment-b can be tagged.

```
[user] $ echo "StoreName exp-a" | /usr/bin/chimera-cli writetag /data/experiment-a OSMTemplate
[user] $ echo "StoreName exp-b" | /usr/bin/chimera-cli writetag /data/experiment-b OSMTemplate
```

Data from experiment-a taken in 2010 shall be written into the directory /data/experiment-a/2010 and data from experiment-a taken in 2011 shall be written into /data/experiment-a/2011. Data from experiment-b shall be written into /data/experiment-b. Tag the directories correspondingly.

```
[user] $ echo "run2010" | /usr/bin/chimera-cli writetag /data/experiment-a/2010 sGroup
[user] $ echo "run2011" | /usr/bin/chimera-cli writetag /data/experiment-a/2011 sGroup
[user] $ echo "alldata" | /usr/bin/chimera-cli writetag /data/experiment-b sGroup
```

List the content of the tags by

```
[user] $ /usr/bin/chimera-cli readtag /data/experiment-a/2010 OSMTemplate
StoreName exp-a
[user] $ /usr/bin/chimera-cli readtag /data/experiment-a/2010 sGroup
run2010
[user] $ /usr/bin/chimera-cli readtag /data/experiment-a/2011 OSMTemplate
StoreName exp-a
[user] $ /usr/bin/chimera-cli readtag /data/experiment-a/2011 sGroup
run2011
[user] $ /usr/bin/chimera-cli readtag /data/experiment-b/2011 OSMTemplate
StoreName exp-a
[user] $ /usr/bin/chimera-cli readtag /data/experiment-b/2011 sGroup
alldata
```

As the tag OSMTemplate was created the HSMType is assumed to be osm.

The storage classes of the files which are copied into these directories after the tags have been set will be

- exp-a:run2010@osm for the files in /data/experiment-a/2010
• **exp-a:run2011@osm** for the files in /data/experiment-a/2011

• **exp-b:alldata@osm** for the files in /data/experiment-b

To see how storage classes are used for pool selection have a look at the example 'Reserving Pools for Storage and Cache Classes' in the PoolManager chapter.

There are more tags used by dCache if the **HSMType** is **enstore**.
Chapter 5. pnfs

Important
This chapter is for existing installations. New installations should use Chimera and not pnfs.

This chapter gives background information about pnfs. pnfs is the filesystem, dCache used to be based on. Only the aspects of pnfs relevant to dCache will be explained here. A complete set of documentation is available from the pnfs homepage [http://www-pnfs.desy.de/].

The Use of pnfs in dCache

dCache uses pnfs as a filesystem and for storing meta-data. pnfs is a filesystem not designed for storage of actual files. Instead, pnfs manages the filesystem hierarchy and standard meta-data of a UNIX filesystem. In addition, other applications (as for example dCache) can use it to store their meta-data. pnfs keeps the complete information in a database.

pnfs implements an NFS server. All the meta-data can be accessed with a standard NFS client, like the one in the Linux kernel. After mounting, normal filesystem operations work fine. However, IO operations on the actual files in the pnfs will normally result in an error.

As a minimum, the pnfs filesystem needs to be mounted only by the server running the dCache core services. In fact, the pnfs server has to run on the same system. For details see (has to be written).

The pnfs filesystem may also be mounted by clients. This should be done by

```
[root] # mount -o intr,hard,rw pnfs-server:/pnfs /pnfs/site.de
```

(assuming the system is configured as described in the installation instructions). Users may then access the meta-data with regular filesystem operations, like `ls -l`, and by the pnfs-specific operations described in the following sections. The files themselves may then be accessed with the dCap protocol (see dCache Book Client Access and Protocols).

Mounting the pnfs filesystem is not necessary for client access to the dCache system if URLs are used to refer to files. In the grid context this is the preferred usage.

Communicating with the pnfs Server

Many configuration parameters of pnfs and the application-specific meta-data is accessed by reading, writing, or creating files of the form `.command(para)`. For example, the following prints the pnfsID of the file `/pnfs/site.de/some/dir/file.dat`:

```
[user] $ cat /pnfs/site.de/any/sub/directory`'(id)(file.dat)'`
0004000000000000002320B8
[user] $
```

From the point of view of the NFS protocol, the file `.id(file.dat)` in the directory `/pnfs/site.de/some/dir/` is read. However, pnfs interprets it as the command `id` with the parameter `file.dat` executed in the directory `/pnfs/site.de/some/dir/`. The quotes are important, because the shell would otherwise try to interpret the parentheses.

Some of these command-files have a second parameter in a third pair of parentheses. Note, that files of the form `.command(para)` are not really files. They are not shown when listing directories with `ls`. However, the command-files are listed when they appear in the argument list of `ls` as in
Only a subset of file operations are allowed on these special command-files. Any other operation will result in an appropriate error. Beware, that files with names of this form might accidentally be created by typos. They will then be shown when listing the directory.

**pnfsIDs**

Each file in *pnfs* has a unique 12 byte long *pnfsID*. This is comparable to the inode number in other filesystems. The *pnfsID* used for a file will never be reused, even if the file is deleted. dCache uses the *pnfsID* for all internal references to a file.

The *pnfsID* of the file *filename* can be obtained by reading the command-file `.(id)(filename)` in the directory of the file.

A file in *pnfs* can be referred to by *pnfsID* for most operations. For example, the name of a file can be obtained from the *pnfsID* with the command `nameof` as follows:

```
[user] $ cd /pnfs/site.de/any/sub/directory/
[user] $ cat '.(nameof)(0004000000000000002320B8)' file.dat
```

And the *pnfsID* of the directory it resides in is obtained by:

```
[user] $ cat '.(parent)(0004000000000000002320B8)'
0004000000000000001DC9E8
```

This way, the complete path of a file may be obtained starting from the *pnfsID*. Precisely this is done by the tool *pathfinder*:

```
[user] $ . /usr/etc/pnfsSetup
[user] $ PATH=$PATH:$pnfs/tools
[user] $ cd /pnfs/site.de/another/dir/
[user] $ pathfinder 00040000000000000002320B8
00040000000000000001DC9E8 directory
000400000000000000001060 sub
000100000000000000001060 any
000000000000000000001080 usr
000000000000000000001040 fs
000000000000000000001020 root
000000000000000000001000 -
000000000000000000000100 -
000000000000000000000000 -
/root/fs/usr/any/sub/directory/file.dat
```

The first two lines configure the *pnfs*-tools correctly. The path obtained by *pathfinder* does not agree with the local path, since the latter depends on the mountpoint (in the example `/pnfs/site.de/`). The *pnfsID* corresponding to the mountpoint may be obtained with

```
[user] $ cat '.(get)(cursor)'
dirID=00040000000000000001DC9E8
dirPerm=00000001400000020
mountID=000000000000000000001080
```

The *dirID* is the *pnfsID* of the current directory and *mountID* that of the mountpoint. In the example, the *pnfs* server path `/root/fs/usr/` is mounted on `/pnfs/site.de/`.  

40
Directory Tags

In the pnfs filesystem, each directory has a number of tags. The existing tags may be listed with

```
[user] $ cat `.(tags)()`
.(tag)(OSMTemplate)
.(tag)(sGroup)
```

and the content of a tag can be read with

```
[user] $ cat `.(tag)(OSMTemplate)`
StoreName myStore
```

A nice trick to list all tags with their contents is

```
[user] $ grep "" $(cat `.(tags)()`)
.(tag)(OSMTemplate):StoreName myStore
.(tag)(sGroup):STRING
```

Directory tags may be used within dCache to control which pools are used for storing the files in the directory (see the section called “The Pool Selection Mechanism”). They might also be used by a tertiary storage system for similar purposes (e.g. controlling the set of tapes used for the files in the directory).

Even if the directory tags are not used to control the behaviour of dCache, some tags have to be set for the directories where dCache files are stored. The installation procedure takes care of this: In the directory `/pnfs/site.de/data/` two tags are set to default values:

```
[user] $ cd /pnfs/site.de/data/
[user] $ grep "" $(cat `.(tags)()`)
.(tag)(OSMTemplate):StoreName myStore
.(tag)(sGroup):STRING
```

The following directory tags appear in the dCache context:

**Directory Tags for dCache**

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OSMTemplate</td>
<td>Contains one line of the form “StoreName storeName” and specifies the name of the store that is used by dCache to construct the storage class if the HSM type is osm.</td>
</tr>
<tr>
<td>hsmType</td>
<td>The HSM type is normally determined from the other existing tags. E.g., if the tag OSMTemplate exists, HSM type osm is assumed. With this tag it can be set explicitly. An class implementing that HSM type has to exist. Currently the only implementations are osm and enstore.</td>
</tr>
<tr>
<td>sGroup</td>
<td>The storage group is also used to construct the storage Class if the HSM type is osm.</td>
</tr>
<tr>
<td>cacheClass</td>
<td>The cache class is only used to control on which pools the files in a directory may be stored, while the storage class (constructed from the two above tags) might also be used by the HSM. The cache class is only needed if the above two tags are already fixed by HSM usage and more flexibility is needed.</td>
</tr>
<tr>
<td>hsmInstance</td>
<td>If not set, the HSM instance will be the same as the HSM type. Setting this tag will only change the name as used in the storage class and in the pool commands.</td>
</tr>
</tbody>
</table>
There are more tags used by dCache if the HSM type enstore is used.

When creating or changing directory tags by writing to the command-file as in

```
[user] $ echo 'content' > '.(tag)(tagName)'
```

one has to take care not to treat the command-files in the same way as regular files, because tags are different from files in the following aspects:

1. The `tagName` is limited to 62 characters and the `content` to 512 bytes. Writing more to the command-file, will be silently ignored.

2. If a tag which does not exist in a directory is created by writing to it, it is called a `primary` tag.

   Removing a primary tag invalidates this tag. An invalidated tag behaves as if it does not exist. All filesystem IO operations on that tag produce an "File not found" error. However, a lookup operation (e.g. ls) will show this tag with a 0 byte size. An invalidated tag can be revalidated with the help of the tool `repairTag.sh` in the `tools/` directory of the pnfs distribution. It has to be called in the directory where the primary tag was with the tag name as argument.

3. Tags are `inherited` from the parent directory by a newly created directory. Changing a primary tag in one directory will change the tags inherited from it in the same way, even if it is invalidated or revalidated. Creating a new primary tag in a directory will not create a inherited tag in its subdirectories.

   Moving a directory within the pnfs filesystem will not change the inheritance. Therefore, a directory does not necessarily inherit tags from its parent directory. Removing an inherited tag does not have any effect.

4. Writing to an inherited tag in the subdirectory will break the inheritance-link. A `pseudo-primary` tag will be created. The directories which inherited the old (inherited) tag will inherit the pseudo-primary tag. A pseudo-primary tag behaves exactly like a primary tag, except that the original inherited tag will be restored if the pseudo-primary tag is removed.

If directory tags are used to control the behaviour of dCache and/or a tertiary storage system, it is a good idea to plan the directory structure in advance, thereby considering the necessary tags and how they should be set up. Moving directories should be done with great care or even not at all. Inherited tags can only be created by creating a new directory.

**Global Configuration with Wormholes**

pnfs provides a way to distribute configuration information to all directories in the pnfs filesystem. It can be accessed in a subdirectory `.config()` of any pnfs-directory. It behaves similar to a hardlink. In the default configuration this link points to `/pnfs/fs/admin/etc/config/`. In it are three files: `'.(config)()'/serverId` contains the domain name of the site, `'.(config)()'/serverName` the fully qualified name of the pnfs server, and `'.(config)()'/serverRoot` should contain “0000000000000000000001080”.

The dCache specific configuration can be found in `'.(config)()'/dCache/dcache.conf`. This file contains one line of the format `hostname:port` per dCap door which may be used by dCap clients when not using URLs. The dccp program will choose randomly between the doors listed here.

Normally, reading from files in pnfs is disabled. Therefore it is necessary to switch on I/O access to the files in `'.(config)()'/` by e.g.:
Deleted Files in `pnfs`

When a file in the `pnfs` filesystem is deleted the server stores information about it in the subdirectories of `/opt/pnfsdb/pnfs/trash/`. For dCache, the cleaner cell in the `pnfsDomain` is responsible for deleting the actual files from the pools asynchronously. It uses the files in the directory `/opt/pnfsdb/pnfs/trash/2/`. It contains a file with the `pnfs` ID of the deleted file as name. If a pool containing that file is down at the time the cleaner tries to remove it, it will retry for a while. After that, the file `/opt/pnfsdb/pnfs/trash/2/current/failed.poolName` will contain the `pnfs` IDs which have not been removed from that pool. The cleaner will still retry the removal with a lower frequency.

Access Control

The files `/pnfs/fs/admin/etc/exports/hostIP` and `/pnfs/fs/admin/etc/exports/netMask..netPart` are used to control the host-based access to the `pnfs` filesystem via mount points. They have to contain one line per NFS mount point. The lines are made of the following four space-separated fields:

- Mount point for NFS (the part after the colon in e.g. `host:/mountpoint`)
- The virtual PNFS path which is mounted
- Permission: 0 means all permissions and 30 means disabled I/O.
- Options (should always be nooptions)

In the initial configuration there is one file `/pnfs/fs/admin/etc/exports/0.0.0.0..0.0.0.0` containing

```
/pnfs /0/root/fs/usr/ 30 nooptions
```

thereby allowing all hosts to mount the part of the `pnfs` filesystem containing the user data. There also is a file `/pnfs/fs/admin/etc/exports/127.0.0.1` containing

```
/fs /0/root/fs 0 nooptions
/admin /0/root/fs/admin 0 nooptions
```

The first line is the mountpoint used by the admin node. If the `pnfs` mount is not needed for client operations (e.g. in the grid context) and if no *tertiary storage system (HSM)* is connected, the file `/pnfs/fs/admin/etc/exports/0.0.0.0..0.0.0.0` may be deleted. With an HSM, the pools which write files into the HSM have to mount the `pnfs` filesystem and suitable export files have to be created.

In general, the user ID 0 of the `root` user on a client mounting the `pnfs` filesystem will be mapped to nobody (not to the user `nobody`). For the hosts whose IP addresses are the file names in the directory `/pnfs/fs/admin/etc/exports/trusted/` this is not the case. The files have to contain only the number 15.
The Databases of pnfs

pnfs stores all the information in GNU dbm database files. Since each operation will lock the database file used globally and since GNU dbm cannot handle database files larger than 2GB, it is advisable to “split” them suitably to future usage. Each database stores the information of a sub-tree of the pnfs filesystem namespace. Which database is responsible for a directory and subsequent subdirectories is determined at creation time of the directory. The following procedure will create a new database and connect a new subdirectory to it.

Each database is handled by a separate server process. The maximum number of servers is set by the variable `shmservers` in file `/usr/etc/pnfsSetup`. Therefore, take care that this number is always higher than the number of databases that will be used (restart pnfs services, if changed).

Prepare the environment with

```
[root] # . /usr/etc/pnfsSetup
[root] # PATH=|$pnfs|/tools:$PATH
```

To get a list of currently existing databases, issue

```
[root] # mdb show
ID Name Type Status Path
-----------------------
0 admin r enabled (r) /opt/pnfsdb/pnfs/databases/admin
1 data1 r enabled (r) /opt/pnfsdb/pnfs/databases/data1
```

Choose a new database name `databaseName` and a location for the database file `databaseFilePath` (just a placeholder for the PostgreSQL version of `pnfs`) and create it with

```
[root] # mdb create databaseName databaseFilePath
```

e.g.

```
[root] # mdb create data2 /opt/pnfsdb/pnfs/databases/data2
```

Make sure the file `databaseFilePath` exists with

```
[root] # touch databaseFilePath
```

This might seem a little strange. The reason is that the PostgreSQL version of the `pnfs` server only uses the file as reference and stores the actual data in the PostgreSQL server.

In order to refresh database information run

```
[root] # mdb update
Starting data2
```

Running command `mdb show` shows the new database:

```
[root] # mdb show
ID Name Type Status Path
-----------------------
0 admin r enabled (r) /opt/pnfsdb/pnfs/databases/admin
1 data1 r enabled (r) /opt/pnfsdb/pnfs/databases/data1
2 data2 r enabled (r) /opt/pnfsdb/pnfs/databases/data2
```
In the `pnfs` filesystem tree, create the new directory in the following way:

```bash
[root] # cd /pnfs/site.de/some/sub/dir/
[root] # mkdir '.(newDbID)(newDirectory)'
```

where `newDbID` is the ID of the new database as listed in the output of `mdb show` and `newDirectory` is the name of the new directory. E.g.

```bash
[root] # cd /pnfs/desy.de/data/zeus/
[root] # mkdir '.(2)(mcdata)'
```

The new database does not know anything about the wormhole `'(config)()'`, yet. For this, the `pnfs` ID of the wormhole directory (`/pnfs/fs/admin/etc/config/`) has to be specified. It can be found out with:

```bash
[root] # sclient getroot ${shmkey} 0
0 000000000000000000001000 wormholePnfsId
```

The last `pnfsID` is the one of the wormhole directory of the database with ID 0 (already set correctly). Now you can set this ID with:

```bash
[root] # sclient getroot ${shmkey} newDbID wormholePnfsId
newDbID 000000000000000000001000 wormholePnfsId
```

For example, do the following:

```bash
[root] # sclient getroot ${shmkey} 0
0 000000000000000000001000 0000000000000000000010E0
[root] # sclient getroot ${shmkey} 2 0000000000000000000010E0
2 000000000000000000001000 0000000000000000000010E0
```

Finally, add directory tags for the new directories. The default tags are added by:

```bash
[root] # cd /pnfs/site.de/some/sub/dir/newDirectory
[root] # echo 'StoreName myStore' > '.(tag)(OSMTemplate)'
[root] # echo 'STRING' > '.(tag)(sGroup)'
```
Chapter 6. The Cell Package

All of dCache makes use of the cell package. It is a framework for a distributed and scalable server system in Java. The dCache system is divided into cells which communicate with each other via messages. Several cells run simultaneously in one domain.

Each domain runs in a separate Java virtual machine and each cell is run as a separate thread therein. Domain names have to be unique. The domains communicate with each other via TCP using connections that are established at start-up. The topology is controlled by the location manager service. In the standard configuration, all domains connect with the dCacheDomain, which routes all messages to the appropriate domains. This forms a star topology.

Only for message communication

The TCP communication controlled by the location manager service is for the short control messages sent between cells. Any transfer of the data stored within dCache does not use these connections; instead, dedicated TCP connections are established as needed.

A single node provides the location-manager service. For a single-host dCache instance, this is localhost; for multi-host dCache instances, the hostname of the node providing this service must be configured using the serviceLocatorHost property.

The domain that hosts the location manager service is also configurable. By default, the service runs within the dCacheDomain domain; however, this may be changed by setting the broker.domain property. The port that the location manager listens on is also configurable, using the serviceLocatorPort property; however, most sites may leave this property unaltered and use the default value.

Within this framework, cells send messages to other cells addressing them in the form cellName@domainName. This way, cells can communicate without knowledge about the host they run on. Some cells are well known, i.e. they can be addressed just by their name without @domainName. Evidently, this can only work properly if the name of the cell is unique throughout the whole system. If two well known cells with the same name are present, the system will behave in an undefined way. Therefore it is wise to take care when starting, naming, or renaming the well known cells. In particular this is true for pools, which are well known cells.

A domain is started with a shell script bin/dcache start domainName. The routing manager and location manager cells are started in each domain and are part of the underlying cell package structure. Each domain will contain at least one cell in addition to them.
Chapter 7. The replica Service (Replica Manager)

The replica service (which is also referred to as Replica Manager) controls the number of replicas of a file on the pools. If no tertiary storage system is connected to a dCache instance (i.e., it is configured as a large file store), there might be only one copy of each file on disk. (At least the precious replica.) If a higher security and/or availability is required, the resilience feature of dCache can be used: If running in the default configuration, the replica service will make sure that the number of replicas of a file will be at least 2 and not more than 3. If only one replica is present it will be copied to another pool by a pool to pool transfer. If four or more replicas exist, some of them will be deleted.

The Basic Setup

The standard configuration assumes that the database server is installed on the same machine as the replica service — usually the admin node of the dCache instance. If this is not the case you need to set the property replicaManagerDatabaseHost.

To create and configure the database replicas used by the replica service in the database server do:

```
[root] # createdb -U srmdcache replicas
[root] # psql -U srmdcache -d replicas -f /usr/share/dcache/replica/psql_install_replicas.sql
```

To activate the replica service you need to

1. Enable the replica service in a layout file.

```
[someDomain]
...
[someDomain/replica]
```

2. Configure the service in the /etc/dcache/dcache.conf file on the node with the dCache-Domain and on the node on which the pnfsmanager is running.

```
replicaManager=yes
```

Note

It will not work properly if you defined the replica service in one of the layout files and set this property to no on the node with the dCacheDomain or on the node on which the pnfsmanager is running.

3. Define a pool group for the resilient pools if necessary.

4. Start the replica service.

In the default configuration, all pools of the dCache instance which have been created with the command dcache pool create will be managed. These pools are in the pool group named default which does exist by default. The replica service will keep the number of replicas between 2 and 3 (including). At each restart of the replica service the pool configuration in the database will be recreated.
The replica Service (Replica Manager)

This is a simple example to get started with. All your pools are assumed to be in the pool group default.

1. In your layout file in the directory /etc/dcache/layouts define the replica service.

```
[dCacheDomain]
...
[replicaDomain]
[replicaDomain/replica]
```

2. In the file /etc/dcache/dcache.conf set the value for the property replicaManager to yes and the resilientGroupName to default.

```
replicaManager=yes
resilientGroupName=default
```

3. The pool group default exists by default and does not need to be defined.

4. To start the replica service restart dCache.

```
[root] # dcache restart
```

Define a poolgroup for resilient pools

For more complex installations of dCache you might want to define a pool group for the resilient pools.

Define the resilient pool group in the /var/lib/dcache/config/poolmanager.conf file on the host running the poolmanager service. Only pools defined in the resilient pool group will be managed by the replica service.

Login to the admin interface and cd to the PoolManager. Define a poolgroup for resilient pools and add pools to that poolgroup.

```
(local) admin > cd PoolManager
(PoolManager) admin > psu create pgroup ResilientPools
(PoolManager) admin > psu create pool pool3
(PoolManager) admin > psu create pool pool4
(PoolManager) admin > psu addto pgroup ResilientPools pool3
(PoolManager) admin > psu addto pgroup ResilientPools pool4
(PoolManager) admin > save
```

By default the pool group named ResilientPools is used for replication.

To use another pool group defined in /var/lib/dcache/config/poolmanager.conf for replication, please specify the group name in the etc/dcache.conf file.

```
resilientGroupName=NameOfResilientPoolGroup.
```

Operation

When a file is transferred into dCache its replica is copied into one of the pools. Since this is the only replica and normally the required range is higher (e.g., by default at least 2 and at most 3), this file will be replicated to other pools.
When some pools go down, the replica count for the files in these pools may fall below the valid range and these files will be replicated. Replicas of the file with replica count below the valid range and which need replication are called *deficient replicas*.

Later on some of the failed pools can come up and bring online more valid replicas. If there are too many replicas for some file these extra replicas are called *redundant replicas* and they will be “reduced”. Extra replicas will be deleted from pools.

The replica service counts the number of replicas for each file in the pools which can be used online (see Pool States below) and keeps the number of replicas within the valid range \((\text{replicaMin}, \text{replicaMax})\).

**Pool States**

The possible states of a pool are **online, down, offline, offline-prepare** and **drainoff**. They can be set by the admin through the admin interface. (See the section called “Commands for the admin interface”.)

**Figure 7.1. Pool State Diagram**

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>online</strong></td>
<td>Normal operation. Replicas in this state are readable and can be counted. Files can be written (copied) to this pool.</td>
</tr>
<tr>
<td><strong>down</strong></td>
<td>A pool can be down because</td>
</tr>
<tr>
<td></td>
<td>- the admin stopped the domain in which the pool was running.</td>
</tr>
<tr>
<td></td>
<td>- the admin set the state value via the admin interface.</td>
</tr>
<tr>
<td></td>
<td>- the pool crashed</td>
</tr>
<tr>
<td><strong>down/transient</strong></td>
<td>To confirm that it is safe to turn pool down there is the command <strong>ls unique</strong> in the admin interface to check number of files which can be locked in this pool. (See the section called “Commands for the admin interface”.)</td>
</tr>
</tbody>
</table>
Replicas in pools which are down are not counted, so when a pool crashes the number of online replicas for some files is reduced. The crash of a pool (pool departure) may trigger replication of multiple files.

On startup, the pool comes briefly to the online state, and then it goes down to do pool “Inventory” to cleanup files which broke when the pool crashed during transfer. When the pool comes online again, the replica service will update the list of replicas in the pool and store it in the database.

Pool recovery (arrival) may trigger massive deletion of file replicas, not necessarily in this pool.

**offline**

The admin can set the pool state to be offline. This state was introduced to avoid unnecessary massive replication if the operator wants to bring the pool down briefly without triggering massive replication.

Replicas in this pool are counted, therefore it does not matter for replication purpose if an offline pool goes down or up.

When a pool comes online from an offline state replicas in the pool will be inventoried to make sure we know the real list of replicas in the pool.

**offline-prepare**

This is a transient state between online and offline.

The admin will set the pool state to be offline-prepare if he wants to change the pool state and does not want to trigger massive replication.

Unique files will be evacuated — at least one replica for each unique file will be copied out. It is unlikely that a file will be locked out when a single pool goes down as normally a few replicas are online. But when several pools go down or set drainoff or offline file lockout might happen.

Now the admin can set the pool state offline and then down and no file replication will be triggered.

**drainoff**

This is a transient state between online and down.

The admin will set the pool state to be drainoff if he needs to set a pool or a set of pools permanently out of operation and wants to make sure that there are no replicas “locked out”.

Unique files will be evacuated — at least one replica for each unique file will be copied out. It is unlikely that a file will be locked out when a single pool goes down as normally a few replicas are online. But when several pools go down or set drainoff or offline file lockout might happen.

Now the admin can set the pool state down. Files from other pools might be replicated now, depending on the values of replicaMin and replicaMax.

**Startup**

When the replica service starts it cleans up the database. Then it waits for some time to give a chance to most of the pools in the system to connect. Otherwise unnecessary massive replication would start. Currently this is implemented by some delay to start adjustments to give the pools a chance to connect.
The \textit{replica} Service (Replica Manager)

\section*{Cold Start}

Normally (during Cold Start) all information in the database is cleaned up and recreated again by polling pools which are online shortly after some minimum delay after the replica service starts. The replica service starts to track the pools’ state (pool up/down messages and polling list of online pools) and updates the list of replicas in the pools which came online. This process lasts for about 10-15 minutes to make sure all pools came up online and/or got connected. Pools which once get connected to the replica service are in online or down state.

It can be annoying to wait for some large period of time until all known “good” pools get connected. There is a “Hot Restart” option to accelerate the restart of the system after the crash of the head node.

\section*{Hot Restart}

On Hot Restart the replica service retrieves information about the pools’ states before the crash from the database and saves the pools’ states to some internal structure. When a pool gets connected the replica service checks the old pool state and registers the old pool’s state in the database again if the state was offline, offline-prepare or drainoff state. The replica service also checks if the pool was online before the crash. When all pools which were online get connected once, the replica service supposes it recovered its old configuration and the replica service starts adjustments. If some pools went down during the connection process they were already accounted and adjustment would take care of it.

Suppose we have ten pools in the system, where eight pools were online and two were offline before a crash. The replica service does not care about the two offline pools to get connected to start adjustments. For the other eight pools which were online, suppose one pool gets connected and then it goes down while the other pools try to connect. The replica service considers this pool in known state, and when the other seven pools get connected it can start adjustments and does not wait any more.

If the system was in equilibrium state before the crash, the replica service may find some deficient replicas because of the crashed pool and start replication right away.

\section*{Avoid replicas on the same host}

For security reasons you might want to spread your replicas such that they are not on the same host, or in the same building or even in the same town. To configure this you need to set the \texttt{tag.hostname} label for your pools and check the properties \texttt{replicaCheckPoolHost} and \texttt{replicaEnableSameHostReplica}.

We assume that some pools of your dCache are in Hamburg and some are in Berlin. In the layout files where the respective pools are defined you can set

\begin{verbatim}
[poolDomain]
[poolDomain/pool1]
name=pool1
path=/srv/dcache/p1
maxDiskSpace=500G
waitForFiles=${path}/data
tag.hostname=Hamburg

and

[poolDomain]
[poolDomain/pool2]
\end{verbatim}
By default the property replicaCheckPoolHost is true and replicaEnableSameHostReplica is false. This means that the tag.hostname will be checked and the replication to a pool with the same tag.hostname is not allowed.

**Hybrid dCache**

A hybrid dCache operates on a combination of pools (maybe connected to tape) which are not in a resilient pool group and the set of resilient pools. The replica service takes care only of the subset of pools configured in the pool group for resilient pools and ignores all other pools.

**Note**

If a file in a resilient pool is marked precious and the pool were connected to a tape system, then it would be flushed to tape. Therefore, the pools in the resilient pool group are not allowed to be connected to tape.

**Commands for the admin interface**

If you are an advanced user, have proper privileges and you know how to issue a command to the admin interface you may connect to the ReplicaManager cell and issue the following commands. You may find more commands in online help which are for debug only — do not use them as they can stop replica service operating properly.

- **set pool poolstate**  
  set pool state

- **show pool pool**  
  show pool state

- **ls unique pool**  
  Reports number of unique replicas in this pool.

- **exclude pnfsId**  
  exclude pnfsId from adjustments

- **release pnfsId**  
  removes transaction/BAD status for pnfsId

- **debug true | false**  
  enable/disable DEBUG messages in the log file

**Properties of the replica service**

- replica/cell.name  
  Default: replicaManager
  
  Cell name of the replica service

- replicaManager  
  Default: no
  
  Set this value to yes if you want to use the replica service.

- resilientGroupName  
  Default: ResilientPools
  
  If you want to use another pool group for the resilient pools set this value to the name of the resilient pool group.

</table>
The replica Service (Replica Manager)

Number of worker threads to do the replication. The same number of worker threads is used for reduction. Must be more for larger systems but avoid situation when requests get queued in the pool.

**replicaMin**
Default: 2

Minimum number of replicas in pools which are online or offline.

**replicaMax**
Default: 3

Maximum number of replicas in pools which are online or offline.

**replicaCheckPoolHost**
Default: true

Checks `tag.hostname` which can be specified in the layout file for each pool.

Set this property to `false` if you do not want to perform this check.

**replicaEnableSameHostReplica**
Default: false

If set to `true` you allow files to be copied to a pool, which has the same `tag.hostname` as the source pool.

**Note**
The property `replicaCheckPoolHost` needs to be set to `true` if `replicaEnableSameHostReplica` is set to `false`. 
Chapter 8. The poolmanager Service

The heart of a dCache system is the poolmanager. When a user performs an action on a file - reading or writing - a transfer request is sent to the dCache system. The poolmanager then decides how to handle this request.

If a file the user wishes to read resides on one of the storage-pools within the dCache system, it will be transferred from that pool to the user. If it resides on several pools, the file will be retrieved from the pool which is least busy. If all pools the file is stored on are busy, a new copy of the file on an idle pool will be created and this pool will answer the request.

A new copy can either be created by a pool to pool transfer (p2p) or by fetching it from a connected tertiary storage system (sometimes called HSM - hierarchical storage manager). Fetching a file from a tertiary storage system is called staging. It is also performed if the file is not present on any of the pools in the dCache system. The pool manager has to decide on which pool the new copy will be created, i.e. staged or p2p-copied.

The behaviour of the poolmanager service is highly configurable. In order to exploit the full potential of the software it is essential to understand the mechanisms used and how they are configured. The poolmanager service creates the PoolManager cell, which is a unique cell in dCache and consists of several sub-modules: The important ones are the pool selection unit (PSU) and the cost manager (CM).

The poolmanager can be configured by either directly editing the file /var/lib/dcache/config/poolmanager.conf or via the Admin Interface. Changes made via the Admin Interface will be saved in the file /var/lib/dcache/config/poolmanager.conf by the save command. This file will be parsed, whenever the dCache starts up. It is a simple text file containing the corresponding Admin Interface commands. It can therefore also be edited before the system is started. It can also be loaded into a running system with the reload command. In this chapter we will describe this file.

The PSU is responsible for finding the pool which will be used for a specific transfer-request based on the information from the CM. By telling the PSU which pools are permitted for which type of transfer-request, the administrator of the dCache system can adjust the system to any kind of scenario: Separate organizations served by separate pools, special pools for writing the data to a tertiary storage system, pools in a DMZ which serves only a certain kind of data (e.g., for the grid). The following section explains the mechanism employed by the PSU and shows how to configure it with several examples.

The Pool Selection Mechanism

The PSU generates a list of allowed storage-pools for each incoming transfer-request. The PSU configuration described below tells the PSU which combinations of transfer-request and storage-pool are allowed. Imagine a two-dimensional table with a row for each possible transfer-request and a column for each pool - each field in the table containing either “yes” or “no”. For an incoming transfer-request the PSU will return a list of all pools with “yes” in the corresponding row.

Instead of “yes” and “no” the table really contains a preference - a non-negative integer. However, the PSU configuration is easier to understand if this is ignored.

Actually maintaining such a table in memory (and as user in a configuration file) would be quite inefficient, because there are many possibilities for the transfer-requests. Instead, the PSU consults a set of rules in order to generate the list of allowed pools. Each such rule is called a link because it links a set of transfer-requests to a group of pools.
Links

A link consists of a set of unit groups and a list of pools. If all the unit groups are matched, the pools belonging to the link are added to the list of allowable pools.

A link is defined in the file /var/lib/dcache/config/poolmanager.conf by

```
psu create link link unitgroup psu set link link -readpref=rpref -writepref=wpref -cachepref=cpref -p2ppref=ppref psu add link link pool
```

For the preference values see the section called “Preference Values for Type of Transfer”.

The main task is to understand how the unit groups in a link are defined. After we have dealt with that, the preference values will be discussed and a few examples will follow.

The four properties of a transfer request, which are relevant for the PSU, are the following:

<table>
<thead>
<tr>
<th>Location of the File</th>
<th>The location of the file in the file system is not used directly. Each file has the following two properties which can be set per directory:</th>
</tr>
</thead>
</table>
|                      | • **Storage Class.** The storage class is a string. It is used by a tertiary storage system to decide where to store the file (i.e. on which set of tapes) and dCache can use the storage class for a similar purpose (i.e. on which pools the file can be stored.). A detailed description of the syntax and how to set the storage class of a directory in the namespace is given in the section called “Storage Classes”.
|                      | • **Cache Class.** The cache class is a string with essentially the same functionality as the storage class, except that it is not used by a tertiary storage system. It is used in cases, where the storage class does not provide enough flexibility. It should only be used, if an existing configuration using storage classes does not provide sufficient flexibility. |
| IP Address           | The IP address of the requesting host. |
| Protocol / Type of Door | The protocol respectively the type of door used by the transfer. |
| Type of Transfer     | The type of transfer is either read, write, p2p request or cache. |

A request for reading a file which is not on a read pool will trigger a p2p request and a subsequent read request. These will be treated as two separate requests.

A request for reading a file which is not stored on disk, but has to be staged from a connected tertiary storage system will trigger a cache request to fetch the file from the tertiary storage system and a subsequent read request. These will be treated as two separate requests.

Each link contains one or more unit groups, all of which have to be matched by the transfer request. Each unit group in turn contains several units. The unit group is matched if at least one of the units is matched.
Types of Units

There are four types of units: network (-net), protocol (-protocol), storage class (-store) and cache class (-dcache) units. Each type imposes a condition on the IP address, the protocol, the storage class and the cache class respectively.

For each transfer at most one of each of the four unit types will match. If more than one unit of the same type could match the request then the most restrictive unit matches.

The unit that matches is selected from all units defined in dCache, not just those for a particular unit group. This means that, if a unit group has a unit that could match a request but this request also matches a more restrictive unit defined elsewhere then the less restrictive unit will not match.

Network Unit

A network unit consists of an IP address and a net mask written as IP-address/net mask, say 111.111.111.0/255.255.255.0. It is satisfied, if the request is coming from a host with IP address within the subnet given by the address/netmask pair.

```
psu create ugroup name-of-unitgroup
psu create unit -net IP-address/net mask
psu addto ugroup name-of-unitgroup IP-address/net mask
```

Protocol Unit

A protocol unit consists of the name of the protocol and the version number written as protocol-name/version-number, e.g., xrootd/3.

```
psu create ugroup name-of-unitgroup
psu create unit -protocol protocol-name/version-number
psu addto ugroup name-of-unitgroup protocol-name/version-number
```

Storage Class Unit

A storage class unit is given by a storage class. It is satisfied if the request-ed file has this storage class. Simple wild cards are allowed: for this it is important to know that a storage class must always contain exactly one @-symbol as will be explained in the section called “Storage Classes”. In a storage class unit, either the part before the @-symbol or both parts may be replaced by a *-symbol; for example, *@osm and *@ are both valid storage class units whereas something*@ is invalid. The *-symbol represents a limited wildcard: any string that doesn’t contain an @-symbol will match.

```
psu create ugroup name-of-unitgroup
psu create unit -store StoreName:StorageGroup&type-of-storage-system
psu addto ugroup name-of-unitgroup StoreName:StorageGroup&type-of-storage-system
```

Cache Class Unit

A cache class unit is given by a cache class. It is satisfied, if the cache class of the requested file agrees with it.

```
psu create ugroup name-of-unitgroup
psu create unit -dcache name-of-cache-class
psu addto ugroup name-of-unitgroup name-of-cache-class
```

Preference Values for Type of Transfer

The conditions for the type of transfer are not specified with units. Instead, each link contains four attributes -readpref, -writepref, -p2ppref and -cachepref, which specify a preference
value for the respective types of transfer. If all the unit groups in the link are matched, the corresponding preference is assigned to each pool the link points to. Since we are ignoring different preference values at the moment, a preference of 0 stands for no and a non-zero preference stands for yes. A negative value for \(-p2ppref\) means, that the value for \(-p2ppref\) should equal the one for \(-readpref\).

**Multiple non-zero Preference Values**

**Note**

This explanation of the preference values can be skipped at first reading. It will not be relevant, if all non-zero preference values are the same. If you want to try configuring the pool manager right now without bothering about the preferences, you should only use 0 (for no) and, say, 10 (for yes) as preferences. You can choose \(-p2ppref=-1\) if it should match the value for \(-readpref\). The first examples below are of this type.

If several different non-zero preference values are used, the PSU will not generate a single list but a set of lists, each containing pools with the same preference. The Cost Manager will use the list of pools with highest preference and select the one with the lowest cost for the transfer. Only if all pools with the highest preference are offline, the next list will be considered by the Cost Manager. This can be used to configure a set of fall-back pools which are used if none of the other pools are available.

**Pool Groups**

Pools can be grouped together to pool groups.

```
psu create pgroup name-of-poolgroup
psu create pool name-of-pool
psu addto pgroup name-of-poolgroup name-of-pool
```

Consider a host pool1 with two pools, pool1_1 and pool1_2, and a host pool2 with one pool pool2_1. If you want to treat them in the same way, you would create a pool group and put all of them in it:

```
psu create pgroup normal-pools
psu create pool pool1_1
psu addto pgroup normal-pools pool1_1
psu create pool pool1_2
psu addto pgroup normal-pools pool1_2
psu create pool pool2_1
psu addto pgroup normal-pools pool2_1
```

If you later want to treat pool1_2 differently from the others, you would remove it from this pool group and add it to a new one:

```
psu removefrom pgroup normal-pools pool1_2
psu create pgroup special-pools
psu create pool pool1_2
psu addto pgroup special-pools pool1_2
```

In the following, we will assume that the necessary pool groups already exist. All names ending with \(-pools\) will denote pool groups.

Note that a pool-node will register itself with the PoolManager: The pool will be created within the PSU and added to the pool group default, if that exists. This is why the dCache system will automatically use any new pool-nodes in the standard configuration: All pools are in default and can therefore handle any request.
Define a link

Now we have everything we need to define a link.

```bash
psu create ugroup name-of-unitgroup
psu create unit - type unit
psu addto ugroup name-of-unitgroup unit

psu create pgroup poolgroup
psu create pool pool
psu addto pgroup poolgroup pool

psu create link link name-of-unitgroup
psu set link link -readpref=10 -writepref=0 -cachepref=10 -p2ppref=-1
psu add link link poolgroup
```

Examples

Find some examples for the configuration of the PSU below.

**Separate Write and Read Pools**

The dCache we are going to configure receives data from a running experiment, stores the data onto a tertiary storage system, and serves as a read cache for users who want to analyze the data. While the new data from the experiment should be stored on highly reliable and therefore expensive systems, the cache functionality may be provided by inexpensive hardware. It is therefore desirable to have a set of pools dedicated for writing the new data and a separate set for reading.

The simplest configuration for such a setup would consist of two links “write-link” and “read-link”. The configuration is as follows:

```bash
psu create pgroup read-pools
psu create pool pool1
psu addto pgroup read-pools pool1
psu create pgroup write-pools
psu create pool pool2
psu addto pgroup write-pools pool2

psu create unit -net 0.0.0.0/0.0.0.0
psu create ugroup allnet-cond
psu addto ugroup allnet-cond 0.0.0.0/0.0.0.0

psu create link read-link allnet-cond
psu set link read-link -readpref=10 -writepref=0 -cachepref=10
psu add link read-link read-pools

psu create link write-link allnet-cond
psu set link write-link -readpref=0 -writepref=10 -cachepref=0
psu add link write-link write-pools
```

Why is the unit group allnet-cond necessary? It is used as a condition which is always true in both links. This is needed, because each link must contain at least one unit group.

**Restricted Access by IP Address**

You might not want to give access to the pools for the whole network, as in the previous example (the section called “Separate Write and Read Pools”), though.

Assume, the experiment data is copied into the cache from the hosts with IP 111.111.111.201, 111.111.111.202, and 111.111.111.203. As you might guess, the subnet of the site is
Access from outside should be denied. Then you would modify the above configuration as follows:

```bash
psu create pgroup read-pools
psu create pool pool1
psu addto pgroup read-pools pool1
psu create pgroup write-pools
psu create pool pool2
psu addto pgroup write-pools pool2

psu create unit -store *@*
psu create unit -net 111.111.111.0/255.255.255.0
psu create unit -net 111.111.111.201/255.255.255.255
psu create unit -net 111.111.111.202/255.255.255.255
psu create unit -net 111.111.111.203/255.255.255.255

psu create ugroup write-cond
psu addto ugroup write-cond 111.111.111.201/255.255.255.255
psu addto ugroup write-cond 111.111.111.202/255.255.255.255
psu addto ugroup write-cond 111.111.111.203/255.255.255.255

psu create ugroup read-cond
psu addto ugroup read-cond 111.111.111.0/255.255.255.0
psu addto ugroup read-cond 111.111.111.201/255.255.255.255
psu addto ugroup read-cond 111.111.111.202/255.255.255.255
psu addto ugroup read-cond 111.111.111.203/255.255.255.255

psu create link read-link read-cond
psu set link read-link -readpref=10 -writelpref=0 -cachepref=10
psu add link read-link read-pools

psu create link write-link write-cond
psu set link write-link -readpref=0 -writelpref=10 -cachepref=0
psu add link write-link write-pools
```

### Important

For a given transfer exactly zero or one storage class unit, cache class unit, net unit and protocol unit will match. As always the most restrictive one will match, the IP 111.111.111.201 will match the 111.111.111.201/255.255.255.255 unit and not the 111.111.111.0/255.255.255.0 unit. Therefore if you only add 111.111.111.0/255.255.255.0 to the unit group “read-cond”, the transfer request coming from the IP 111.111.111.201 will only be allowed to write and not to read. The same is true for transfer requests from 111.111.111.202 and 111.111.111.203.

### Reserving Pools for Storage and Cache Classes

If pools are financed by one experimental group, they probably do not like it if they are also used by another group. The best way to restrict data belonging to one experiment to a set of pools is with the help of storage class conditions. If more flexibility is needed, cache class conditions can be used for the same purpose.

Assume, data of experiment A obtained in 2010 is written into subdirectories in the namespace tree which are tagged with the storage class `exp-a:run2010@osm`, and similarly for the other years. (How this is done is described in the section called “Storage Classes”). Experiment B uses the storage class `exp-b:alldata@osm` for all its data. Especially important data is tagged with the cache class `important`. (This is described in the section called “Cache Class”). A suitable setup would be:

```bash
psu create pgroup exp-a-pools
psu create pool pool1
psu addto pgroup exp-a-pools pool1

psu create pgroup exp-b-pools
```
The poolmanager Service

Data tagged with cache class “important” will always be written and read from pools in the pool group exp-b-imp-pools, except when all pools in this group cannot be reached. Then the pools in exp-a-pools will be used.

Note again that these will never be used otherwise. Not even, if all pools in exp-b-imp-pools are very busy and some pools in exp-a-pools have nothing to do and lots of free space.

The central IT department might also want to set up a few pools, which are used as fall-back, if none of the pools of the experiments are functioning. These will also be used for internal testing. The following would have to be added to the previous setup:

Note again that these will only be used, if none of the experiments pools can be reached, or if the storage class is not of the form exp-a:run2009@osm, exp-a:run2010@osm, or exp-b:alldata@osm. If the administrator fails to create the unit exp-a:run2005@osm and add it to the unit group exp-a-cond, the fall-back pools will be used eventually.

Storage Classes

The storage class is a string of the form StoreName:StorageGroup@type-of-storage-system, where type-of-storage-system denotes the type of storage system in use, and
StoreName:StorageGroup is a string describing the storage class in a syntax which depends on the storage system. In general use type-of-storage-system=osm.

Consider for example the following setup:

```
[root] # /usr/bin/chimera-cli lstag /data/experiment-a
Total: 2
OSMTemplate
sGroup
[root] # /usr/bin/chimera-cli readtag /data/experiment-a OSMTemplate
StoreName myStore
[root] # /usr/bin/chimera-cli readtag /data/experiment-a sGroup
STRING
```

This is the setup after a fresh installation and it will lead to the storage class myStore:STRING@osm. An adjustment to more sensible values will look like

```
[root] # echo "StoreName exp-a" | /usr/bin/chimera-cli Writetag /data/experiment-a OSMTemplate
[root] # echo "run2010" | /usr/bin/chimera-cli Writetag /data/experiment-a sGroup
```

and will result in the storage class exp-a:run2010@osm. To summarize: The storage class will depend on the directory the data is stored in and is configurable.

**Cache Class**

Storage classes might already be in use for the configuration of a tertiary storage system. In most cases they should be flexible enough to configure the PSU. However, in rare cases the existing configuration and convention for storage classes might not be flexible enough.

Consider for example a situation, where data produced by an experiment always has the same storage class exp-a:alldata@osm. This is good for the tertiary storage system, since all data is supposed to go to the same tape set sequentially. However, the data also contains a relatively small amount of meta-data, which is accessed much more often by analysis jobs than the rest of the data. You would like to keep the meta-data on a dedicated set of dCache pools. However, the storage class does not provide means to accomplish that.

The cache class of a directory is set by the tag cacheClass as follows:

```
[root] # echo "metaData" > ".(tag)(cacheClass)"
```

In the above example the meta-data is stored in directories which are tagged in this way.

There is a nice trick for easy checking of the existing tags in one directory:

```
[root] # grep '' `cat '.(tags)'`
.(tag)(OSMTemplate):StoreName exp-a
.(tag)(sGroup):run2010
.(tag)(cacheClass):MetaData
```

This only works, if the quote-symbols are used correctly. (tick, tick, back-tick, tick, tick, back-tick).

Tags are inherited by sub-directories: Changing a tag of a directory will change the tag of each sub-directory, if the tag has never been changed for this sub-directory directly. Changing tags breaks these inheritance links. Directories in namespace should never be moved, since this will mess up the inheritance structure and eventually break the whole system.
Link Groups

The PoolManager supports a type of objects called link groups. These link groups are used by the SRM SpaceManager to make reservations against space. Each link group corresponds to a number of dCache pools in the following way: A link group is a collection of links and each link points to a set of pools. Each link group knows about the size of its available space, which is the sum of all sizes of available space in all the pools included in this link group.

To create a new link group login to the Admin Interface and cd to the PoolManager.

```
(local) admin > cd PoolManager
(PoolManager) admin > psu create linkGroup linkgroup
(PoolManager) admin > psu addto linkGroup linkgroup link
(PoolManager) admin > save
```

With save the changes will be saved to the file /etc/dcache/PoolManager.conf.

**Note**

You can also edit the file /etc/dcache/PoolManager.conf to create a new link group. Please make sure that it already exists. Otherwise you will have to create it first via the Admin Interface by

```
(PoolManager) admin > save
```

Edit the file /etc/dcache/PoolManager.conf

```
psu create linkGroup linkgroup
psu addto linkGroup linkgroup link
```

After editing this file you will have to restart the domain which contains the PoolManager cell to apply the changes.

**Note**

Administrators will have to take care, that a pool is not present in more than one link group.

**Properties of space reservation.** The dCache administrator can specify a RetentionPolicy and an AccessLatency for the space reservation, where RetentionPolicy describes the quality of the storage service that will be provided for the data (files) stored in this space reservation and AccessLatency describes the availability of this data.

A link group has five boolean properties called replicaAllowed, outputAllowed, custodialAllowed, onlineAllowed and nearlineAllowed. The values of these properties (true or false) can be configured via the Admin Interface or directly in the file /opt/d-cache/config/PoolManager.conf.

The link groups contained in a space reservation match the RetentionPolicy and the AccessLatency of the space reservation.

```
(PoolManager) admin > psu set linkGroup custodialAllowed linkgroup true|false
(PoolManager) admin > psu set linkGroup outputAllowed linkgroup true|false
(PoolManager) admin > psu set linkGroup replicaAllowed linkgroup true|false
(PoolManager) admin > psu set linkGroup onlineAllowed linkgroup true|false
```
Moreover an attribute can be assigned to a link group.

Possible assignments for attributes are:

```
(PoolManager) admin > psu set linkGroup attribute linkgroup key=value

(PoolManager) admin > psu set linkGroup attribute name-of-LinkGroup VO=dteam001
(PoolManager) admin > psu set linkGroup attribute name-of-LinkGroup VO=cms001
(PoolManager) admin > psu set linkGroup attribute name-of-LinkGroup HSM=osm
```

Note

Please note that it is up to administrators that the link groups’ attributes are specified correctly.

For example dCache will not complain if the link group that does not support tape backend will be declared as one that supports custodial.

**The Cost Module**

From the allowable pools as determined by the pool selection unit, the pool manager determines the pool used for storing or reading a file by calculating a cost value for each pool. The pool with the lowest cost is used.

If a client requests to read a file which is stored on more than one allowable pool, the performance costs are calculated for these pools. In short, this cost value describes how much the pool is currently occupied with transfers.

If a pool has to be selected for storing a file, which is either written by a client or restored from a tape backend, this performance cost is combined with a space cost value to a total cost value for the decision. The space cost describes how much it “hurts” to free space on the pool for the file.

The cost module is responsible for calculating the cost values for all pools. The pools regularly send all necessary information about space usage and request queue lengths to the cost module. It can be regarded as a cache for all this information. This way it is not necessary to send “get cost” requests to the pools for each client request. The cost module interpolates the expected costs until a new precise information package is coming from the pools. This mechanism prevents clumping of requests.

Calculating the cost for a data transfer is done in two steps. First, the cost module merges all information about space and transfer queues of the pools to calculate the performance and space costs separately. Second, in the case of a write or stage request, these two numbers are merged to build the total cost for each pool. The first step is isolated within a separate loadable class. The second step is done by the cost module.

**The Performance Cost**

The load of a pool is determined by comparing the current number of active and waiting transfers to the maximum number of concurrent transfers allowed. This is done separately for each of the transfer types (store, restore, pool-to-pool client, pool-to-pool server, and client request) with the following equation:

\[
\text{perfCost} \text{(per Type)} = \frac{(\text{activeTransfers} + \text{waitingTransfers})}{\text{maxAllowed}}.
\]
The maximum number of concurrent transfers (maxAllowed) can be configured with the commands `st set max active` (store), `rh set max active` (restore), `mover set max active` (client request), `mover set max active -queue=p2p` (pool-to-pool server), and `pp set max active` (pool-to-pool client).

Then the average is taken for each mover type where maxAllowed is not zero. For a pool where store, restore and client transfers are allowed, e.g.,

\[
\text{perfCost}(\text{total}) = \left( \frac{\text{perfCost}(\text{store}) + \text{perfCost}(\text{restore}) + \text{perfCost}(\text{client})}{3} \right),
\]

and for a read only pool:

\[
\text{perfCost}(\text{total}) = \left( \frac{\text{perfCost}(\text{restore}) + \text{perfCost}(\text{client})}{2} \right).
\]

For a well balanced system, the performance cost should not exceed 1.0.

**The Space Cost**

In this section only the new scheme for calculating the space cost will be described. Be aware, that the old scheme will be used if the breakeven parameter of a pool is larger or equal 1.0.

The cost value used for determining a pool for storing a file depends either on the free space on the pool or on the age of the least recently used (LRU) file, which would have to be deleted.

The space cost is calculated as follows:

\[
\begin{align*}
\text{If } \text{freeSpace} & > \text{gapPara} \quad \text{then } \text{spaceCost} = 3 \times \frac{\text{newFileSize}}{\text{freeSpace}} \\
\text{If } \text{freeSpace} & \leq \text{gapPara} \quad \text{and } \text{lruAge} < 60 \quad \text{then } \text{spaceCost} = 1 + \frac{\text{costForMinute}}{} \\
\text{If } \text{freeSpace} & \leq \text{gapPara} \quad \text{and } \text{lruAge} \geq 60 \quad \text{then } \text{spaceCost} = 1 + \frac{\text{costForMinute} \times 60}{\text{lruAge}}
\end{align*}
\]

where the variable names have the following meanings:

- **freeSpace** The free space left on the pool
- **newFileSize** The size of the file to be written to one of the pools, and at least 50MB.
- **lruAge** The age of the least recently used file on the pool.
- **gapPara** The gap parameter. Default is 4GB. The size of free space below which it will be assumed that the pool is full and consequently the least recently used file has to be removed. If, on the other hand, the free space is greater than gapPara, it will be expensive to store a file on the pool which exceeds the free space.

It can be set per pool with the `set gap` command. This has to be done in the pool cell and not in the pool manager cell. Nevertheless it only influences the cost calculation scheme within the pool manager and not the behaviour of the pool itself.

- **costForMinute** A parameter which fixes the space cost of a one-minute-old LRU file to \((1 + \text{costForMinute})\). It can be set with the `set breakeven`, where

\[
\text{costForMinute} = \text{breakeven} \times 7 \times 24 \times 60.
\]

I.e. the space cost of a one-week-old LRU file will be \((1 + \text{breakeven})\). Note again, that all this only applies if breakeven < 1.0
The poolmanager Service

The prescription above can be stated a little differently as follows:

If \( \text{freeSpace} > \text{gapPara} \) then \( \text{spaceCost} = 3 \times \text{newFileSize} / \text{freeSpace} \)

If \( \text{freeSpace} \leq \text{gapPara} \) then \( \text{spaceCost} = 1 + \text{breakeven} \times 7 \times 24 \times 60 \times 60 / \text{lruAge} \),

where \( \text{newFileSize} \) is at least 50MB and \( \text{lruAge} \) at least one minute.

**Rationale**

As the last version of the formula suggests, a pool can be in two states: Either \( \text{freeSpace} > \text{gapPara} \) or \( \text{freeSpace} \leq \text{gapPara} \) - either there is free space left to store files without deleting cached files or there isn’t.

Therefore, \( \text{gapPara} \) should be around the size of the smallest files which frequently might be written to the pool. If files smaller than \( \text{gapPara} \) appear very seldom or never, the pool might get stuck in the first of the two cases with a high cost.

If the LRU file is smaller than the new file, other files might have to be deleted. If these are much younger than the LRU file, this space cost calculation scheme might not lead to a selection of the optimal pool. However, in praxis this happens very seldomly and this scheme turns out to be very efficient.

**The Total Cost**

The total cost is a linear combination of the *performance* and *space cost*. I.e. \( \text{totalCost} = \text{ccf} \times \text{perfCost} + \text{scf} \times \text{spaceCost} \), where \( \text{ccf} \) and \( \text{scf} \) are configurable with the command set pool decision. E.g.,

```
{PoolManager} admin > set pool decision -spacecostfactor=3 -cpucostfactor=1
```

will give the *space cost* three times the weight of the *performance cost*. 

Chapter 9. The dCache Tertiary Storage System Interface

Introduction

One of the features dCache provides is the ability to migrate files from its disk repository to one or more connected Tertiary Storage Systems (TSS) and to move them back to disk when necessary. Although the interface between dCache and the TSS is kept simple, dCache assumes to interact with an intelligent TSS. dCache does not drive tape robots or tape drives by itself. More detailed requirements to the storage system are described in one of the subsequent paragraphs.

Scope of this chapter

This document describes how to enable a standard dCache installation to interact with a Tertiary Storage System. In this description we assume that

• every dCache disk pool is connected to only one TSS instance.
• all dCache disk pools are connected to the same TSS instance.
• the dCache instance has not yet been populated with data, or only with a negligible amount of files.

In general, not all pools need to be configured to interact with the same Tertiary Storage System or with a storage system at all. Furthermore pools can be configured to have more than one Tertiary Storage System attached, but all those cases are not in the scope of the document.

Requirements for a Tertiary Storage System

dCache can only drive intelligent Tertiary Storage Systems. This essentially means that tape robot and tape drive operations must be done by the TSS itself and that there is some simple way to abstract the file PUT, GET and REMOVE operation.

Migrating Tertiary Storage Systems with a file system interface.

Most migrating storage systems provide a regular POSIX file system interface. Based on rules, data is migrated from primary to tertiary storage (mostly tape systems). Examples for migrating storage systems are:

• HPSS [http://www.hpss-collaboration.org/] (High Performance Storage System)
• DMF [http://www.sgi.com/products/storage/software/dfm.html] (Data Migration Facility)
Tertiary Storage Systems with a minimalistic **PUT**, **GET** and **REMOVE** interface

Some tape systems provide a simple **PUT**, **GET**, **REMOVE** interface. Typically, a copy-like application writes a disk file into the TSS and returns an identifier which uniquely identifies the written file within the Tertiary Storage System. The identifier is sufficient to get the file back to disk or to remove the file from the TSS. Examples are:

- OSM [http://www.qstar.com/qstar-products/qstar-object-storage-manager] (Object Storage Manager)
- Enstore [http://www-ccf.fnal.gov/enstore/] (FERMIlab)

How dCache interacts with a Tertiary Storage System

Whenever dCache decides to copy a file from disk to tertiary storage a user-provided executable which can be either a script or a binary is automatically started on the pool where the file is located. That executable is expected to write the file into the Backend Storage System and to return a URI, uniquely identifying the file within that storage system. The format of the URI as well as the arguments to the executable, are described later in this document. The unique part of the URI can either be provided by the storage element, in return of the **STORE FILE** operation, or can be taken from dCache. A non-error return code from the executable lets dCache assume that the file has been successfully stored and, depending on the properties of the file, dCache can decide to remove the disk copy if space is running short on that pool. On a non-zero return from the executable, the file doesn’t change its state and the operation is retried or an error flag is set on the file, depending on the error return code from the executable.

If dCache needs to restore a file to disk the same executable is launched with a different set of arguments, including the URI, provided when the file was written to tape. It is in the responsibility of the executable to fetch the file back from tape based on the provided URI and to return 0 if the **FETCH FILE** operation was successful or non-zero otherwise. In case of a failure the pool retries the operation or dCache decides to fetch the file from tape using a different pool.

Details on the TSS-support executable

Summary of command line options

This part explains the syntax of calling the executable that supports **STORE FILE**, **FETCH FILE** and **REMOVE FILE** operations.

**put** `pnfsID` `filename` `-si=` `storage-information` `[other-options...]`

**get** `pnfsID` `filename` `-si=` `storage-information` `-uri=` `storage-uri` `[other-options...]`

**remove** `-uri=` `storage-uri` `[other-options...]`

- **put / get / remove**: these keywords indicate the operation to be performed.
  - **put**: copy file from disk to TSS.
  - **get**: copy file back from TSS to disk.
• **remove**: remove the file from TSS.

• **pnfsID**: The internal identifier (i-node) of the file within dCache. The *pnfsID* is unique within a single dCache instance and globally unique with a very high probability.

• **filename**: is the full path of the local file to be copied to the TSS (for **put**) and respectively into which the file from the TSS should be copied (for **get**).

• **storage-information**: the storage information of the file, as explained below.

• **storage-uri**: the URI, which was returned by the **executable**, after the file was written to tertiary storage. In order to get the file back from the TSS the information of the URI is preferred over the information in the **storage-information**.

• **other-options**: `-key = value` pairs taken from the TSS configuration commands of the pool 'setup' file. One of the options, always provided is the option `-command=full path of this executable`.

### Storage Information

The **storage-information** is a string in the format

```plaintext
-si=size=bytes;new=true/false;stored=true/false;sClass=StorageClass;\n cClass=CacheClass;hsm=StorageType;key=value;[key=value;[...]]
```

```
-si=size=1048576000;new=true;stored=false;sClass=desy-cms-sc3;cClass=-;hsm=osm;Host=desy;
```

#### Mandatory storage information’s keys

• **size**: Size of the file in bytes

• **new**: *False* if file already in the dCache; *True* otherwise

• **stored**: *True* if file already stored in the TSS; *False* otherwise

• **sClass**: HSM depended, is used by the **poolmanager** for pool attraction.

• **cClass**: Parent directory tag (cacheClass). Used by the **poolmanager** for pool attraction. May be `-`.

• **hsm**: Storage manager name (enstore/osm). Can be overwritten by the parent directory tag (hsmType).

#### OSM specific storage information’s keys

• **group**: The storage group of the file to be stored as specified in the `".(tag)(sGroup)"` tag of the parent directory of the file to be stored.

• **store**: The store name of the file to be stored as specified in the `".(tag)(OSMTemplate)"` tag of the parent directory of the file to be stored.

• **bfid**: Bitfile ID (get and remove only) (e.g. `000451243.2542452542.25424524`)

#### Enstore specific storage information’s keys

• **group**: The storage group (e.g. cdf, cms ...)

• **family**: The file family (e.g. sgi2test, h6nxl8, ...)
The dCache Tertiary Storage System Interface

- **bfid**: Bitfile ID (get only) (e.g. B0MS105746894100000)
- **volume**: Tape Volume (get only) (e.g. IA6912)
- **location**: Location on tape (get only) (e.g.: 0000_000000000_0000117)

There might be more key values pairs which are used by the dCache internally and which should not affect the behaviour of the executable.

### Storage URI

The **storage-uri** is formatted as follows:

```
hsmType://hsmInstance/?store=storename&group=groupname&bfid=bfid
```

- **hsmType**: The type of the Tertiary Storage System
- **hsmInstance**: The name of the instance
- **storename** and **groupname**: The store and group name of the file as provided by the arguments to this executable.
- **bfid**: The unique identifier needed to restore or remove the file if necessary.

A storage-uri:

```
osm://osm/?store=sql&group=chimera&bfid=3434.0.994.1188400818542
```

### Summary of return codes

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Meaning</th>
<th>Behaviour for PUT FILE</th>
<th>Behaviour for GET FILE</th>

</tbody>
</table>

### The executable and the STORE FILE operation

Whenever a disk file needs to be copied to a Tertiary Storage System dCache automatically launches an executable on the pool containing the file to be copied. Exactly one instance of the executable is started for each file. Multiple instances of the executable may run concurrently for different files. The maximum number of concurrent instances of the executables per pool as well as the full path
of the executable can be configured in the 'setup' file of the pool as described in the section called
"The pool 'setup' file".

The following arguments are given to the executable of a STORE FILE operation on startup.

\texttt{put \textit{pnfsID} \textit{filename} \textit{-si=}\textit{storage-information} \textit{more options}}

Details on the meaning of certain arguments are described in the section called "Summary of command
line options".

With the arguments provided the executable is supposed to copy the file into the Tertiary Storage
System. The executable must not terminate before the transfer of the file was either successful or
failed.

Success must be indicated by a 0 return of the executable. All non-zero values are interpreted as a
failure which means, dCache assumes that the file has not been copied to tape.

In case of a 0 return code the executable has to return a valid storage URI to dCache in format:

\begin{verbatim}
\texttt{hsmType://hsmInstance/?store=storename\&group=groupname\&bfid=bfid}
\end{verbatim}

Details on the meaning of certain parameters are described above.

The \textit{bfid} can either be provided by the TSS as result of the STORE FILE operation or the \textit{pnfsID}
may be used. The latter assumes that the file has to be stored with exactly that \textit{pnfsID} within the TSS.
Whatever URI is chosen, it must allow to uniquely identify the file within the Tertiary Storage System.

\textbf{Note}

Only the URI must be printed to stdout by the executable. Additional information printed
either before or after the URI will result in an error. stderr can be used for additional debug
information or error messages.

\section*{The executable and the FETCH FILE operation}

Whenever a disk file needs to be restored from a Tertiary Storage System dCache automatically launches
an executable on the pool containing the file to be copied. Exactly one instance of the executable
is started for each file. Multiple instances of the executable may run concurrently for different files.
The maximum number of concurrent instances of the executable per pool as well as the full path
of the executable can be configured in the 'setup' file of the pool as described in the section called
"The pool 'setup' file".

The following arguments are given to the executable of a FETCH FILE operation on startup:

\texttt{get \textit{pnfsID} \textit{filename} \textit{-si=}\textit{storage-information} \textit{-uri=}\textit{storage-uri} \textit{more options}}

Details on the meaning of certain arguments are described in the section called "Summary of command
line options". For return codes see the section called "Summary of return codes".

\section*{The executable and the REMOVE FILE operation}

Whenever a file is removed from the dCache namespace (file system) a process inside dCache makes sure
that all copies of the file are removed from all internal and external media. The pool which is connected to
the TSS which stores the file is activating the executable with the following command line options:

\texttt{remove \textit{-uri=}\textit{storage-uri} \textit{more options}}

Details on the meaning of certain arguments are described in the section called "Summary of command
line options". For return codes see the section called "Summary of return codes".
The executable is supposed to remove the file from the TSS and report a zero return code. If a non-zero error code is returned, the dCache will call the script again at a later point in time.

### Configuring pools to interact with a Tertiary Storage System

The executable interacting with the Tertiary Storage System (TSS), as described in the chapter above, has to be provided to dCache on all pools connected to the TSS. The executable, either a script or a binary, has to be made “executable” for the user, dCache is running as, on that host.

The following files have to be modified to allow dCache to interact with the TSS.

- The `/var/lib/dcache/config/poolmanager.conf` file (one per system)
- The pool layout file (one per pool host)
- The pool 'setup' file (one per pool)
- The namespaceDomain layout file (one per system)

After the layout files and the various 'setup' files have been corrected, the following domains have to be restarted:

- pool services
- dCacheDomain
- namespaceDomain

### The dCache layout files

#### The `/var/lib/dcache/config/poolmanager.conf` file

To be able to read a file from the tape in case the cached file has been deleted from all pools, enable the restore-option. The best way to do this is to log in to the Admin Interface and run the following commands:

```plaintext
[example.dcache.org] (local) admin > cd PoolManager
[example.dcache.org] (PoolManager) admin > pm set -stage-allowed=yes
[example.dcache.org] (PoolManager) admin > save
```

A restart of the dCacheDomain is not necessary in this case.

Alternatively, if the file `/var/lib/dcache/config/poolmanager.conf` already exists then you can add the entry

```
pm set -stage allowed=yes
```

and restart the dCacheDomain.

**Warning**

Do not create the file `/var/lib/dcache/config/poolmanager.conf` with this single entry! This will result in an error.
The pool layout

The dCache layout file must be modified for each pool node connected to a TSS. If your pool nodes have been configured correctly to work without TSS, you will find the entry lfs=precious in the layout file (that is located in /etc/dcache/layouts and in the file /etc/dcache/dcache.conf respectively) for each pool service. This entry is a disk-only-option and has to be removed for each pool which should be connected to a TSS. This will default the lfs parameter to hsm which is exactly what we need.

The pool 'setup' file

The pool 'setup' file is the file $poolHomeDir/$poolName/setup. It mainly defines 3 details related to TSS connectivity.

- Pointer to the executable which is launched on storing and fetching files.
- The maximum number of concurrent STORE FILE requests allowed per pool.
- The maximum number of concurrent FETCH FILE requests allowed per pool.

Define the executable and Set the maximum number of concurrent PUT and GET operations:

```
  hsm set hsmType [hsmInstanceName] [-command=/path/to/executable] [-key=value]
```

- `hsmType`: the type of the TSS system. Must be set to “osm” for basic setups.
- `hsmInstanceName`: the instance name of the TSS system. Must be set to “osm” for basic setups.
- `/path/to/executable`: the full path to the executable which should be launched for each TSS operation.

Setting the maximum number of concurrent PUT and GET operations.

Both numbers must be non zero to allow the pool to perform transfers.

We provide a script to simulate a connection to a TSS. To use this script place it in the directory /usr/share/dcache/lib, and create a directory to simulate the base of the TSS.

```
[root] # mkdir -p /hsmTape/data
```

Login to the Admin Interface to change the entry of the pool 'setup' file for a pool named pool_1.

```
(pool_1) admin > cd pool_1
(pool_1) admin > hsm set osm osm
(pool_1) admin > hsm set osm -command=/usr/share/dcache/lib/hsmscript.sh
(pool_1) admin > hsm set osm -hsmBase=/hsmTape
(pool_1) admin > st set max active 5
(pool_1) admin > rh set max active 5
(pool_1) admin > save
```
The namespace layout

In order to allow dCache to remove files from attached TSSes, the “cleaner.hsm = enabled” must be added immediately underneath the [namespaceDomain/cleaner] service declaration:

```
[namespaceDomain]
  ...
[namespaceDomain/cleaner]
cleaner.hsm = enabled
  ...
```

What happens next

After restarting the necessary dCache domains, pools, already containing files, will start transferring them into the TSS as those files only have a disk copy so far. The number of transfers is determined by the configuration in the pool ‘setup’ file as described above in the section called “The pool ‘setup’ file”.

How to Store-/Restore files via the Admin Interface

In order to see the state of files within a pool, login into the pool in the admin interface and run the command `rep ls`.

```
[example.dcache.org] {poolname} admin > rep ls
```

The output will have the following format:

```
PNFSID <MODE-BITS(LOCK-TIME)|OPEN-COUNT> SIZE si={STORAGE-CLASS}
```

- **PNFSID**: The `pnfsID` of the file
- **MODE-BITS**:
  
<table>
<thead>
<tr>
<th>CPCsRDXEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
</tr>
<tr>
<td>E</td>
</tr>
<tr>
<td>X</td>
</tr>
<tr>
<td>D</td>
</tr>
<tr>
<td>R</td>
</tr>
<tr>
<td>S</td>
</tr>
<tr>
<td>C</td>
</tr>
<tr>
<td>P</td>
</tr>
<tr>
<td>T</td>
</tr>
</tbody>
</table>

- **LOCK-TIME**: The number of milli-seconds this file will still be locked. Please note that this is an internal lock and not the pin-time (SRM).
- **OPEN-COUNT**: Number of clients currently reading this file.
- **SIZE**: File size
- **STORAGE-CLASS**: The storage class of this file.
The dCache Tertiary Storage System Interface

In order to flush a file to the tape run the command `flush pnfsid`.

```bash
[example.dcache.org] (pool_1) admin > flush pnfsid
```

A file that has been flushed to tape gets the flag 'C'.

```bash
[example.dcache.org] (pool_1) admin > rep ls
```

To remove such a file from the repository run the command `rep rm`.

```bash
[example.dcache.org] (pool_1) admin > rep rm
```

In this case the file will be restored when requested.

To restore a file from the tape you can simply request it by initializing a reading transfer or you can fetch it by running the command `rh restore`.

```bash
[example.dcache.org] (pool_1) admin > rh restore
```

How to monitor what’s going on

This section briefly describes the commands and mechanisms to monitor the TSS PUT, GET and REMOVE operations. dCache provides a configurable logging facility and a Command Line Admin Interface to query and manipulate transfer and waiting queues.

Log Files

By default dCache is configured to only log information if something unexpected happens. However, to get familiar with Tertiary Storage System interactions you might be interested in more details. This section provides advice on how to obtain this kind of information.

The executable log file

Since you provide the executable, interfacing dCache and the TSS, it is in your responsibility to ensure sufficient logging information to be able to trace possible problems with either dCache or the TSS. Each request should be printed with the full set of parameters it receives, together with a timestamp. Furthermore information returned to dCache should be reported.
dCache log files in general

In dCache, each domain (e.g. dCacheDomain, poolDomain etc) prints logging information into its own log file named after the domain. The location of those log files it typically the /var/log or /var/log/dCache directory depending on the individual configuration. In the default logging setup only errors are reported. This behavior can be changed by either modifying /etc/dcache/logback.xml or using the dCache CLI to increase the log level of particular components as described below.

Increase the dCache log level by changes in /etc/dcache/logback.xml

If you intend to increase the log level of all components on a particular host you would need to change the /etc/dcache/logback.xml file as described below. dCache components need to be restarted to activate the changes.

```
<threshold>
  <appender>stdout</appender>
  <logger>root</logger>
  <level>warn</level>
</threshold>
```

needs to be changed to

```
<threshold>
  <appender>stdout</appender>
  <logger>root</logger>
  <level>info</level>
</threshold>
```

Important

The change might result in a significant increase in log messages. So don’t forget to change back before starting production operation. The next section describes how to change the log level in a running system.

Increase the dCache log level via the Command Line Admin Interface

Login into the dCache Command Line Admin Interface and increase the log level of a particular service, for instance for the poolmanager service:

```
[example.dcache.org] (local) admin > cd PoolManager
[example.dcache.org] (PoolManager) admin > log set stdout ROOT INFO
[example.dcache.org] (PoolManager) admin > log ls
stdout:
ROOT=INFO
dmg.cells.nucleus=WARN*
logger.org.dcache.cells.messages=ERROR*
.....
```

Obtain information via the dCache Command Line Admin Interface

The dCache Command Line Admin Interface gives access to information describing the process of storing and fetching files to and from the TSS, as there are:
The dCache Tertiary Storage System Interface

- The **Pool Manager Restore Queue**. A list of all requests which have been issued to all pools for a FETCH FILE operation from the TSS (rc ls).

- The **Pool Collector Queue**. A list of files, per pool and storage group, which will be scheduled for a STORE FILE operation as soon as the configured trigger criteria match.

- The **Pool STORE FILE Queue**. A list of files per pool, scheduled for the STORE FILE operation. A configurable amount of requests within this queue are active, which is equivalent to the number of concurrent store processes, the rest is inactive, waiting to become active.

- The **Pool FETCH FILE Queue**. A list of files per pool, scheduled for the FETCH FILE operation. A configurable amount of requests within this queue are active, which is equivalent to the number of concurrent fetch processes, the rest is inactive, waiting to become active.

For evaluation purposes, the pinboard of each component can be used to track down dCache behavior. The pinboard only keeps the most recent 200 lines of log information but reports not only errors but informational messages as well.

Check the pinboard of a service, here the poolmanager service.

```bash
[example.dcache.org] (local) admin > cd PoolManager
[example.dcache.org] (PoolManager) admin > show pinboard 100
08.30.45 [Thread-7] [pool_1 PoolManagerPoolUp] sendPoolStatusRelay: ...
08.30.59 [writeHandler] [NFSv41-dcachetogo PoolMgrSelectWritePool ... ....
```

**The PoolManager Restore Queue.** Remove the file test.root with the pnfs-ID 00002A9282C2D7A147C68A327208173B81A6.

```bash
[example.dcache.org] (pool_1) admin > rep rm 00002A9282C2D7A147C68A327208173B81A6
```

Request the file test.root

```bash
[user] $ dccp dcap://example.dcache.org:/data/test.root test.root
```

**Check the PoolManager Restore Queue:**

```bash
[example.dcache.org] (local) admin > cd PoolManager
[example.dcache.org] (PoolManager) admin > rc ls
00000A1260F474554142BA976D0DAF78C6C80.0.0.0.0/0.0.0.0-%/* m=1 r=0 [pool_1] [Staging 08.15 17:52:16]
```

**The Pool Collector Queue.**

```bash
[example.dcache.org] (pool_1) admin > queue ls -l queue
Name: chimera:alpha
  Class@Hsm: chimera:alpha@osm
  Expiration rest/defined: -39 / 0 seconds
  Pending rest/defined: 1 / 0

Chapter 10. File Hopping

File hopping is a collective term in dCache, summarizing the possibility of having files being transferred between dCache pools triggered by a variety of conditions. The most prominent examples are:

- If a file is requested by a client but the file resides on a pool from which this client, by configuration, is not allowed to read data, the dataset is transferred to an “allowed” pool first.

- If a pool encounters a steady high load, the system may, if configured, decide to replicate files to other pools to achieve an equal load distribution.

- HSM restore operations may be split into two steps. The first one reads data from tertiary storage to an “HSM connected” pool and the second step takes care that the file is replicated to a general read pool. Under some conditions this separation of HSM and non-HSM pools might become necessary for performance reasons.

- If a dataset has been written into dCache it might become necessary to have this file replicated instantly. The reasons can be, to either have a second, safe copy, or to make sure that clients don’t access the file for reading on the write pools.

**File Hopping on arrival from outside dCache**

*File Hopping on arrival* is a term, denoting the possibility of initiating a pool to pool transfer as the result of a file successfully arriving on a pool from some external client. Files restored from HSM or arriving on a pool as the result of a pool to pool transfer will not yet be forwarded.

Forwarding of incoming files can be enabled by setting the `replicateOnArrival` property in the `/etc/dcache/dcache.conf` file or per pool in the layout file. It can be set to `on`, `PoolManager` or `HoppingManager`, where `on` does the same as `PoolManager`.

The pool is requested to send a `replicateFile` message to either the `PoolManager` or to the `HoppingManager`, if available. The different approaches are briefly described below and in more detail in the subsequent sections.

- The `replicateFile` message is sent to the `PoolManager`. This happens for all files arriving at that pool from outside (no restore or p2p). No intermediate `HoppingManager` is needed. The restrictions are
  - All files are replicated. No pre-selection, e.g. on the storage class can be done.
  - The mode of the replicated file is determined by the destination pool and cannot be overwritten. See the section called “File mode of replicated files”

- The `replicateFile` message is sent to the `HoppingManager`. The `HoppingManager` can be configured to replicate certain storage classes only and to set the mode of the replicated file according to rules. The file mode of the source file cannot be modified.

**File mode of replicated files**

The mode of a replicated file can either be determined by settings in the destination pool or by the `HoppingManager`. It can be `cached` or `precious`.  

83
• If the PoolManager is used for replication, the mode of the replicated file is determined by the destination pool. The default setting is cached.

• If a HoppingManager is used for file replication, the mode of the replicated file is determined by the HoppingManager rule responsible for this particular replication. If the destination mode is set to keep in the rule, the mode of the destination pool determines the final mode of the replicated file.

File Hopping managed by the PoolManager

To enable replication on arrival by the PoolManager set the property replicateOnArrival to on for the particular pool

```bash
[exampleDomain]
[exampleDomain/pool]
... 
replicateOnArrival=on
```

or for several pools in the /etc/dcache/dcache.conf file.

```bash
... 
replicateOnArrival=on
```

File hopping configuration instructs a pool to send a replicateFile request to the PoolManager as the result of a file arriving on that pool from some external client. All arriving files will be treated the same. The PoolManager will process this transfer request by trying to find a matching link (Please find detailed information at Chapter 8, The poolmanager Service.

It is possible to configure the PoolManager such that files are replicated from this pool to a special set of destination pools.

Assume that we want to have all files, arriving on pool ocean to be immediately replicated to a subset of read pools. This subset of pools is described by the poolgroup ocean-copies. No other pool is member of the poolgroup ocean-copies.

Other than that, files arriving at the pool mountain should be replicated to all read pools from which farm nodes on the 131.169.10.0/24 subnet are allowed to read.

The layout file defining the pools ocean and mountain should read like this:

```bash
[exampleDomain]
[exampleDomain/pool]
name=ocean
path=/path/to/pool-ocean
waitForFiles=${path}/data
replicateOnArrival=on

name=mountain
path=/path/to/pool-mountain
waitForFiles=${path}/data
replicateOnArrival=on
```

In the layout file it is defined that all files arriving on the pools ocean or mountain should be replicated immediately. The following PoolManager.conf file contains instructions for the PoolManager how to replicate these files. Files arriving at the ocean pool will be replicated to the ocean-copies subset of the read pools and files arriving at the pool mountain will be replicated to all read pools from which farm nodes on the 131.169.10.0/24 subnet are allowed to read.

```bash
# 
```
# define the units
#

File Hopping

While 131.169.10.1 is a legal IP address e.g. of one of your farm nodes, the 192.1.1.1 IP address must not exist anywhere at your site.

File Hopping managed by the HoppingManager

With the HoppingManager you have several configuration options for file hopping on arrival, e.g.:

- With the HoppingManager you can define a rule such that only the files with a specific storage class should be replicated.
- You can specify the protocol the replicated files can be accessed with.
- You can specify from which ip-addresses it should be possible to access the files.

Starting the FileHopping Manager service

Add the hopping service to a domain in your layout file and restart the domain.

```
[DomainName]
[DomainName]/hopping
```

Initially no rules are configured for the HoppingManager. You may add rules by either edit the file /var/lib/dcache/config/HoppingManager.conf and restart the hopping service, or use the admin interface and save the modifications by the save command into the HoppingManager.conf

Configuring pools to use the HoppingManager

To enable replication on arrival by the HoppingManager set the property replicateOnArrival to HoppingManager for the particular pool

```
[exampleDomain]
[exampleDomain/pool]
...
replicateOnArrival=HoppingManager
```

or for several pools in the /etc/dcache/dcache.conf file.

```
...
replicateOnArrival=HoppingManager
```
**HoppingManager Configuration Introduction**

- The **HoppingManager** essentially receives `replicateFile` messages from pools, configured to support file hopping, and either discards or modifies and forwards them to the **PoolManager**, depending on rules described below.

- The **HoppingManager** decides on the action to perform, based on a set of configurable rules. Each rule has a name. Rules are checked in alphabetic order concerning their names.

- A rule is triggered if the storage class matches the storage class pattern assigned to that rule. If a rule is triggered, it is processed and no further rule checking is performed. If no rule is found for this request the file is not replicated.

- If for whatever reason, a file cannot be replicated, NO RETRY is being performed.

- Processing a triggered rule can be:
  - The message is discarded. No replication is done for this particular storage class.
  - The rule modifies the `replicateFile` message, before it is forwarded to the **PoolManager**.

  An ip-number of a farm-node of the farm that should be allowed to read the file can be added to the `replicateFile` message.

  The mode of the replicated file can be specified. This can either be `precious`, `cached` or `keep`. `keep` means that the pool mode of the source pool determines the replicated file mode.

  The requested protocol can be specified.

**HoppingManager Configuration Reference**

```bash
define hop OPTIONS name pattern precious|cached|keep
 OPTIONS
 -destination=cellDestination # default : PoolManager
 -overwrite
 -continue
 -source=write|restore|* # !!!! for experts only StorageInfoOptions
 -host=destinationHostIp
 -protType=dCap|ftp...
 -protMinor=minorProtocolVersion
 -protMajor=majorProtocolVersion
```

- **name**
  - This is the name of the hopping rule. Rules are checked in alphabetic order concerning their names.

- **pattern**
  - Pattern is a storage class pattern. If the incoming storage class matches this pattern, this rule is processed.

- **precious|cached|keep**
  - `precious|cached|keep` determines the mode of the replicated file. With `keep` the mode of the file will be determined by the mode of the destination pool.

- **-destination**
  - This defines which `cell` to use for the pool to pool transfer. By default this is the **PoolManager** and this should not be changed.

- **-overwrite**
  - In case, a rule with the same name already exists, it is overwritten.
-continue

If a rule has been triggered and the corresponding action has been performed, no other rules are checked. If the continue option is specified, rule checking continues. This is for debugging purposes only.

-source

-source defines the event on the pool which has triggered the hopping. Possible values are restore and write. restore means that the rule should be triggered if the file was restored from a tape and write means that it should be triggered if the file was written by a client.

-host

Choose the id of a node of the farm of worker-nodes that should be allowed to access the file. Configure the poolmanager respectively.

-protType, -protMajor, -protMinor

Specify the protocol which should be used to access the replicated files.

**HoppingManager configuration examples**

In order to instruct a particular pool to send a replicateFile message to the hopping service, you need to add the line replicateOnArrival=HoppingManager to the layout file.

```bash
[exampleDomain]
[exampleDomain/pool]
name=write-pool
path=/path/to/write-pool-exp-a
waitForFiles=${path}/data
replicateOnArrival=HoppingManager
...
```

Assume that all files of experiment-a will be written to an expensive write pool and subsequently flushed to tape. Now some of these files need to be accessed without delay. The files that need fast access possibility will be given the storage class exp-a:need-fast-access@osm.

In this example we will configure the file hopping such that a user who wants to access a file that has the above storage info with the NFSv4.1 protocol will be able to do so.

Define a rule for hopping in the /var/lib/dcache/config/HoppingManager.conf file.

```bash
define hop nfs-hop exp-a:need-fast-access@osm cached -protType=nfs -protMajor=4 -protMinor=1
```

This assumes that the storage class of the file is exp-a:nfs@osm. The mode of the file, which was precious on the write pool will have to be changed to cached on the read pool.

The corresponding /var/lib/dcache/config/poolmanager.conf file could read like this:

```bash
# define the units
#
psu create unit -protocol /*
psu create unit -net 0.0.0.0/0.0.0.0
psu create unit -store exp-a:need-fast-access@osm
#
# define unit groups
#
```
psu create ugroup any-protocol
psu create ugroup exp-a-copy-store
psu create ugroup allnet-cond
#
psu addto ugroup any-protocol */*
psu addto ugroup exp-a-copy-store exp-a:need-fast-access@osm
psu addto ugroup allnet-cond 0.0.0.0/0.0.0.0
#
#
define the write-pool
#
psu create pool write-pool
#
#define the read-pool
psu create pool read-pool
#
#define the exp-a-read-pools poolgroup and add a pool
psu create pgroup exp-a-read-pools
psu addto pgroup exp-a-read-pools read-pool
#
#define the exp-a-write-pools poolgroup and add a pool
psu create pgroup exp-a-write-pools
psu addto pgroup exp-a-write-pools write-pool
#
#define the exp-a-read-link, add exp-a-read-pools and set transfer preferences
psu create link exp-a-read-link exp-a-copy-store any-protocol allnet-cond
psu addto link exp-a-read-link exp-a-read-pools
psu set link exp-a-read-link -readpref=10 -writepref=0 -cachepref=10 -p2ppref=-1
#
#define the exp-a-write-link, add exp-a-write-pools and set transfer preferences
psu create link exp-a-write-link exp-a-copy-store any-protocol allnet-cond
psu addto link exp-a-write-link exp-a-write-pools
psu set link exp-a-write-link -readpref=0 -writepref=10 -cachepref=0 -p2ppref=-1
#
#
Chapter 11. dCache Partitioning

There are various parameters in the dCache PoolManager subsystem, determining the system behaviour on particular events. These are for example the cost threshold at which the PoolManager initiates pool to pool transfers to smooth the overall system load, or the balance between performance and disk space related costs to optimize request distribution among data pools. A defined set of parameters can have different values for different partitions of the complete dCache instance. dCache provides a web page, listing partitions, assigned parameters and inheritance information.

Parameters, partitions and inheritance

Parameters, currently part of the partitioning scheme, are listed within the next paragraph, together with a way of assigning values. Each of those parameters may be set to different values for different, so called dCache partitions.

The only partition, existing without being created, is the default partition. All partitions can be created or modified. If only a subset of parameters of a non default partition is defined, the residual parameters of this partition are inherited from the default partition. So, changing a parameter in the default partition, will change the same parameter of all other partitions for which this particular parameter has not been overwritten.

Commands related to dCache partitioning:

• pm create [partitionName]
  creates a new partition.

• pm set [partitionName]-parameterName [=value|off]
  sets a parameter parameterName to a new value. If partitionName is omitted, the default partition is used.

  If partitionName doesn’t exist yet, it is (silently) created.

  Warning
  This can cause problems: If you want to set a value for a partition and misspell the partition name a new partition will be created. Therefore this feature will be removed.

  If a parameter is set to off this parameter is no longer overwritten and is inherited from the default partition. Setting a value to off for the default partition does not have any effect.

• pm ls [-l] [partitionName]
  lists a single or all partitions. Except for the default, only those parameters are shown which are explicitly set. Parameters, not shown, are inherited from the default partition.

• pm destroy partitionName
  completely removes a partition from dCache.

In the Web Interface you can find a web page listing partitions and more information. You will find a page summarizing the partition status of the system. This is essentially the output of the command pm ls -l.

For your dCache on example.org the address is

http://dcache.example.org:2288/poolInfo/parameterHandler/set/matrix/*
dCache Partitioning

Partition Parameters

The following list describes which parameters may be used in conjunction with dCache partitioning.

Recall that the total cost of a pool is a linear combination of the performance and space cost. It is calculated by

\[ \text{totalCost} = ccf \times \text{perfCost} + scf \times \text{spaceCost} \]

where the cpu cost factor \( ccf \) and the space cost factor \( scf \) are configurable with the command \texttt{pm set}.

\[ \text{pm set} \text{-spacecostfactor=\textit{value} \text{-cpucostfactor=\textit{value}}} \]

Note

Using the command \texttt{pm set} without specifying a partition leads to changes in the default partition.

To set these and more values see the table below.

\( value = 0.0 \) implies that the feature is disabled.

\( value = \text{off} \) implies that the value is inherited from the default section.

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{pm set [partitionName]} -spacecostfactor=\textit{scf} \text{-cpucostfactor=\textit{ccf}}</td>
<td>Sets the space cost factor for the partition. The default value is 1.0.</td>
<td>float</td>
</tr>
<tr>
<td>\texttt{pm set [partitionName]} -idle=\textit{idle-value}</td>
<td>The concept of the idle value will be turned on if \textit{idle-value} ( &gt; 0.0 ). A pool is idle if its performance cost is smaller than the idle-value. Otherwise it is not idle. If one or more pools that satisfy the read request are idle then only one of them is chosen for a particular file irrespective of total cost. I.e. if the same file is requested more than once it will always be taken from the same pool. This allows the copies on the other pools to age and be garbage collected. The default value is 0.0, which disables this feature.</td>
<td>float</td>
</tr>
<tr>
<td>\texttt{pm set [partitionName]} -p2p=\textit{p2p-value}</td>
<td>Sets the static replication threshold for the partition. If the performance cost on the best pool exceeds ( p2p-value ) and the value for \textit{slope} = 0.0 then this pool is called hot and a pool to pool replication may be triggered. The default value is 0.0, which disables this feature.</td>
<td>float</td>
</tr>
<tr>
<td>Command</td>
<td>Meaning</td>
<td>Type</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>pm set [partitionName] -alert=value</td>
<td>Sets the <em>alert value</em> for the partition. If the best pool’s performance cost exceeds the p2p value and the alert value then no pool to pool copy is triggered and a message will be logged stating that no pool to pool copy will be made. The default value is 0.0, which disables this feature.</td>
<td>float</td>
</tr>
<tr>
<td>pm set [partitionName] -panic=value</td>
<td>Sets the <em>panic cost cut level</em> for the partition. If the performance cost of the best pool exceeds the panic cost cut level the request will fail. The default value is 0.0, which disables this feature.</td>
<td>float</td>
</tr>
<tr>
<td>pm set [partitionName] -fallback=value</td>
<td>Sets the fallback cost cut level for the partition. If the best pool’s performance cost exceeds the fallback cost cut level then a pool of the next level will be chosen. This means for example that instead of choosing a pool with readpref = 20 a pool with readpref &lt; 20 will be chosen. The default value is 0.0, which disables this feature.</td>
<td>float</td>
</tr>
<tr>
<td>pm set [partitionName] -slope=slope</td>
<td>Sets the dynamic replication threshold value for the partition. If <em>slope</em> &gt; 0.01 then the product of best pool’s performance cost and <em>slope</em> is used as threshold for pool to pool replication. If the performance cost on the best pool exceeds this threshold then this pool is called hot. The default value is 0.0, which disables this feature.</td>
<td>float</td>
</tr>
<tr>
<td>pm set [partitionName] -p2p-allowed=value</td>
<td>This value can be specified if an HSM is attached to the dCache. If a partition has no HSM connected, then this option is overridden. This means that no matter which value is set for p2p-allowed the pool to pool replication will always be allowed. By setting <em>value</em> = off the values for p2p-allowed, p2p-oncost and p2p-fortransfer will take over the value of the default partition. If <em>value</em> = yes then pool to pool replication is allowed. As a side effect of setting <em>value</em> = no the values for p2p-oncost and p2p-fortransfer will also be set to no.</td>
<td>boolean</td>
</tr>
</tbody>
</table>
## dCache Partitioning

<table>
<thead>
<tr>
<th>Command</th>

<td>pm set [partitionName] -p2p-oncost=value</td>
<td>Determines whether pool to pool replication is allowed if the best pool for a read request is hot.</td>
<td>boolean</td>
</tr>
<tr>
<td>pm set [partitionName] -p2p-fortransfer=value</td>
<td>If the best pool is hot and the requested file will be copied either from the hot pool or from tape to another pool, then the requested file will be read from the pool where it just had been copied to if value = yes. If value = no then the requested file will be read from the hot pool.</td>
<td>boolean</td>
</tr>
<tr>
<td>pm set [partitionName] -stage-allowed=value</td>
<td>Set the stage allowed value to yes if a tape system is connected and to no otherwise. As a side effect, setting the value for stage-allowed to no changes the value for stage-oncost to no.</td>
<td>boolean</td>
</tr>
<tr>
<td>pm set [partitionName] -stage-oncost=value</td>
<td>If the best pool is hot, p2p-oncost is disabled and an HSM is connected to a pool then this parameter determines whether to stage the requested file to a different pool.</td>
<td>boolean</td>
</tr>
<tr>
<td>pm set [partitionName] -max-copies=copies</td>
<td>Sets the maximal number of replicas of one file. If the maximum is reached no more replicas will be created.</td>
<td>integer</td>
</tr>
</tbody>
</table>

### Partitions and Links

A partition, so far, is just a set of parameters which may or may not differ from the default set. To let a partition relate to a part of the dCache, links are used. Each link may be assigned to exactly one partition. If not set, or the assigned partition doesn’t exist, the link defaults to the default partition.

```
psu set link [linkName] -section=partitionName [other-options...]
```

Whenever this link is chosen for pool selection, the associated parameters of the assigned partition will become active for further processing.

**Warning**

Depending on the way links are setup it may very well happen that more than just one link is triggered for a particular dCache request. This is not illegal but leads to an ambiguity in selecting an appropriate dCache partition. If only one of the selected links has a partition assigned, this partition is chosen. Otherwise, if different links point to different partitions, the result is indeterminate. This issue is not yet solved and we recommend to clean up the poolmanager configuration to eliminate links with the same preferences for the same type of requests.
Examples

For the subsequent examples we assume a basic poolmanager setup:

```
# define the units
psu create -protocol */*
psu create -protocol xrootd/*
psu create -net 0.0.0.0/0.0.0.0
psu create -net 131.169.0.0/255.255.0.0
psu create -store *@*

# define unit groups
psu create ugroup any-protocol
psu create ugroup any-store
psu create ugroup world-net
psu create ugroup xrootd

# psu addto ugroup any-protocol */*
psu addto ugroup any-store *@*
psu addto ugroup world-net 0.0.0.0/0.0.0.0
psu addto ugroup desy-net 131.169.0.0/255.255.0.0
psu addto ugroup xrootd xrootd/*

# define the pools
psu create pool pool1
psu create pool pool2

# define the pool groups
psu create pgroup default-pools
psu create pgroup special-pools

# psu addto pgroup default-pools pool1
psu addto pgroup default-pools pool2

# psu addto pgroup special-pools pool1
psu addto pgroup special-pools pool2
```

Disallowing pool to pool transfers for special pool groups based on the access protocol

For a special set of pools, where we only allow the xrootd protocol, we don’t want the datasets to be replicated on high load while for the rest of the pools we allow replication on hot spot detection.

```
# pm set default -p2p=0.4
pm set xrootd-section -p2p=0.0

# psu create link default-link any-protocol any-store world-net -p2p=0.0
psu set link default-link default-pools
psu set link default-link -readpref=10 -cachepref=10 -writepref=0

# psu create link xrootd-link xrootd any-store world-net
psu add link xrootd-link special-pools
psu set link xrootd-link -readpref=11 -cachepref=11 -writepref=0
psu set link xrootd-link -section=xrootd-section
```
Choosing pools randomly for incoming traffic only

For a set of pools we select pools following the default setting of cpu and space related cost factors. For incoming traffic from outside, though, we select the same pools, but in a randomly distributed fashion. Please note that this is not really a physical partitioning of the dCache system, but rather a virtual one, applied to the same set of pools.

```bash
# pm set default          -cpucostfactor=0.2 -spacecostfactor=1.0
pm set incoming-section -cpucostfactor=0.0 -spacecostfactor=0.0
#
psu create link default-link any-protocol any-store desy-net
psu add    link default-link default-pools
psu set    link default-link -readpref=10 -cachepref=10 -writepref=10
#
psu create link default-link any-protocol any-store world-net
psu add    link default-link default-pools
psu set    link default-link -readpref=10 -cachepref=10 -writepref=0
#
psu create link incoming-link any-protocol any-store world-net
psu add    link incoming-link default-pools
psu set    link incoming-link -readpref=10 -cachepref=10 -writepref=10
psu set    link incoming-link -section=incoming-section
#```
Chapter 12. Authorization in dCache

dCache has an open interface to work with different authorization services. With dCache you get two implementations of this interface: gPlazma1 and gPlazma2. Both are described in this chapter. gPlazma is an acronym for Grid-aware PLuggable AuthorZation Management. Both implementations come with various plug-ins that implement different authorization methods (e.g., Username/Password). gPlazma1 is grown over the last few years and provides with some older authorization methods gPlazma2 does not. On the other hand: gPlazma2 has a more modular structure, offers the possibility to add custom plug-ins and is able to make use of some authorization techniques you cannot use with gPlazma1 (i.e., centralised banning of users). Also gPlazma2 has an new PAM like configuration system that makes configuration very easy.

Read the following sections and see which version matches your needs best. If both do, we recommend to use gPlazma2. For legacy reasons version 1 is used as default. To set the version set gplazma.version property in /etc/dcache/dcache.conf to 1 or 2.

```
gplazma.version = 2
```

The recommended way to specify the version is to set it in dcache.conf, but if you prefer you might as well do it in the layout file.

```
[gPlazmaDomain]
[gPlazmaDomain/gplazma]
gplazma.version = 2
```

**Note**

If you don’t explicitly set the version to 2 then gPlazma1 will be used.

**Basics**

Though it is possible to allow anonymous access to dCache it is usually desirable to authenticate users. The user then has to connect to one of the different doors (e.g., GridFTP door, dCap door) and login with credentials that prove his identity. These credentials usually are X.509 certificates, but dCache also supports username/password and kerberos authentication.

The door collects the credential information from the user and sends a login request to the configured authorization service (in most cases this is gPlazma and we will go on assuming it is). Within gPlazma the configured plug-ins try to verify the users identity and determine his access rights. From this a response is created that is then sent back to the door. The response may also contain additional user information like UID, GID and the path to the data directory. While for authentication usually more global services (e.g., ARGUS) may be used, the mapping to site specific UIDs has to be configured on a per site basis. Both versions of gPlazma come with several plug-ins. Their configuration is described in the section called “Configuration files”.

**gPlazma1**

gPlazma1 comes with support for five different authentication and mapping methods. Each method is implemented in a plug-in-like module.
Authorization in dCache

**Configuration**

The gPlazma cell can be called from the GridFTP door and the dCap door and the srm server.

This section describes how to configure gPlazma in general. You also need to adjust the plug-in specific configuration files, depending on which authorization methods you choose to employ. The configuration of the plug-ins is described later in this chapter, since the files are also used by gPlazma2.

The gPlazma policy, located in the `/etc/dcache/dcachesrm-gplazma.policy` file, controls the authorization plug-ins to be used (ON or OFF for each plug-in) and the order of their execution.

```plaintext
# Switches
xacml-vo-mapping="OFF"
saml-vo-mapping="ON"
kpwd="ON"
grid-mapfile="OFF"
gplazmalite-vorole-mapping="OFF"

# Priorities
xacml-vo-mapping-priority="5"
saml-vo-mapping-priority="1"
kpwd-priority="3"
grid-mapfile-priority="4"
gplazmalite-vorole-mapping-priority="2"
```

The order of execution is specified by assigning a different number to each plug-in, such as

```plaintext
# Switches
xacml-vo-mapping="OFF"
saml-vo-mapping="ON"
kpwd="ON"
grid-mapfile="OFF"
gplazmalite-vorole-mapping="OFF"

# Priorities
xacml-vo-mapping-priority="5"
saml-vo-mapping-priority="1"
kpwd-priority="3"
grid-mapfile-priority="4"
gplazmalite-vorole-mapping-priority="2"
```

In the above example, only the saml-vo-mapping plug-in and the kpwd plug-in are activated (i.e., switched ON). Of those the saml-vo-mapping plug-in would be tried first, because it was assigned a higher priority. Note that the higher the value the lower is the plugins priority. If authorization was denied for that method, or if the authentication method itself failed, then the next activated plugin with the next lower priority would be tried. In this example this would be the kpwd plug-in. If the gplazmalite-vorole-mapping plug-in would also be activated, it would be tried after the saml-vo-mapping plug-in and before the kpwd plug-in.

Activating more than one plug-in allows plug-ins to be used as fall-back for another plug-ins that may fail. It also allows for the authorization of special users who may be denied by the other methods.

After the general configuration the policy file also contains a section for each of the plug-ins with plug-in specific configuration. These sections are described in the documentation for each plug-in, as follows. You may delete or comment out the lines specifying the priorities and configuration for unused plug-ins.

Here is an example of how a policy file might be set up.

```plaintext
# Switches
xacml-vo-mapping="OFF"
saml-vo-mapping="ON"
kpwd="ON"
grid-mapfile="OFF"
gplazmalite-vorole-mapping="OFF"

# Priorities
xacml-vo-mapping-priority="5"
saml-vo-mapping-priority="1"
kpwd-priority="3"
grid-mapfile-priority="4"
gplazmalite-vorole-mapping-priority="2"

# dcache.kpwd
kpwdPath="/etc/dcache/dcache.kpwd"

# SAML-based grid VO role mapping
```
In this case, gPlazma1 will attempt to authorize first through a GUMS server, and fall back to using dcache.kpwd. The mappingServiceUrl would have to be changed to a GUMS server appropriate for the site.

### Configuring VOMS Attribute Validation

VOMS attribute validation in gPlazma1 does not require VOMS server certificates. Instead the signature of an attribute is checked against the CA Certificate that signed the VOMS server certificate. To have gPlazma1 validate the proxy attributes in dCache, write configuration directories and *.lsc files in /etc/grid-security/vomsdir for each authorized VOMS server according to these instructions [https://twiki.cern.ch/twiki/bin/view/LCG/VomsFAQforServiceManagers] and set the vomsValidation in /etc/dcache/dcachesrm-gplazma.policy to true.

**Note**

The legacy method of using *.pem files which contain the VOMS server certificates is still supported. To achieve this add the *.pem file which contains the certificate of the VOMS server to the directory /etc/grid-security/vomsdir/.

Note that it is recommended to use the *.lsc files for the VOMS attribute validation as with this method you don’t need to keep the VOMS server certificate up to date.

The default is to validate the attributes. In both cases there must be a non-empty /etc/grid-security/vomsdir directory on the node which is running gPlazma1. To create a working dummy directory it is enough to do

```
[root] # mkdir -p /etc/grid-security/vomsdir
[root] # touch /etc/grid-security/vomsdir/empty-cert.pem
```

### plug-ins

This section describes the five different authentication methods for gPlazma1. Four of them share the common file storage-authzdb for mapping usernames to UID/GID and provide additional user specific path information. The format of this file is described in the section called "storage-authzdb".

**gplazmalite-vorole-mapping plug-in**

The gplazmalite-vorole-mapping plug-in maps a combination of DN and FQAN (Fully Qualified Attribute Name) to a username using a vorolemap file. The subsequent mappings to UID and GID is done via the storage-authzdb file.

**kpwd plug-in**

The kpwd plug-in uses a kpwd file for authorization and mapping. This is the “legacy” method and is recommended only for testing and/or rather small and independent sites or as a fallback method. The file contains different records for authorization and mappings. Its format is documented within the sample file in /usr/share/dcache/examples/gplazma/dcache.kpwd. In the first step a DN or Kerberos principal is mapped to a username. To authorize the user has to provide the password belonging to the mapped username to get UID and GID and user path information.
grid-mapfile plug-in

This plug-in uses a grid-mapfile to map DNs to usernames. The subsequent mapping to UID/GID is done via the storage-authzdb file.

saml-vo-mapping plug-in

This plug-in requests DN to username mappings from a GUMS server (Grid User Management System). The GUMS service may run an extension which returns the UID/GID plus the additional user path information. Without this extension UID and GID are obtained via the storage-authzdb file.

xacml-vo-mapping plug-in

This plug-in requests DN to username mappings from a GUMS server with XACML support. The GUMS service may run an extension which returns the UID/GID plus the additional user path information. Without this extension UID and GID are obtained via the storage-authzdb (see the section called “storage-authzdb”) file.

gPlazma2

Some newer requirements (e.g., reverse mapping, banning) could not be integrated into gPlazma1 without making major changes on its architecture. Since the effort would have only been slightly less than a reimplementation, we decided to keep the established gPlazma1 and create a new version from scratch that could offer modern features for those who already require them. In the long term gPlazma2 is meant to replace gPlazma1 completely. For this reason it supports most of the latter’s authentication methods. But not only offers gPlazma2 new features, it also comes with flexible architecture that can be extended by plug-ins. Since many authentication methods share some functionality (e.g., use storage-authdb) the same functionality that was covered by one plug-in in version 1 is now divided into several plug-ins. This way, if for example you used the gplazmalite-vorole-mapping plug-in of gPlazma1 you will now need to use the vorolemap plug-in and the authzdb plug-in to get the same functionality. Currently gPlazma2 comes with seven plug-ins that can be used to cover a wide range of systems. Check if yours is among those. Some plug-ins are designed for backwards compatibility and will work with your existing files (e.g., vorolemap) and some offer completely new functionality (e.g., NIS/LDAP mapping, ARGUS banning).

gPlazma2 has several advantages over gPlazma1 in means of design, flexibility and functionality. Its behaviour is easily configurable with a PAM-style configuration file, that will be described in detail in the next section.

Configuration

To use gPlazma2, the first thing you have to do is to activate it by setting gplazma.version to 2 in dcache.conf. This is described in the first part of this chapter. Afterwards edit /etc/dcache/gplazma.conf with your favourite editor (e.g., vim) to match your requirements. The plug-ins will be used in the order auth, map, account and session. Within these groups they are used in the order they are specified.

It will look something like this:

```
# Some comment
auth optional x509
auth optional voms
```
Authorization in dCache

<table>
<thead>
<tr>
<th>map</th>
<th>requisite vorolemap</th>
</tr>
</thead>
<tbody>
<tr>
<td>map</td>
<td>requisite authzdb authzdb=/etc/grid-security/authzdb</td>
</tr>
<tr>
<td>session</td>
<td>requisite authzdb</td>
</tr>
</tbody>
</table>

Each line consists of one of the keywords auth, map, account, session or identity followed by one of the modifiers optional, required, requisite or sufficient, the name of the plug-in and a list of parameters. Empty lines and lines starting with a # are comments and will be ignored.

With the first keyword you specify the type of the plugin (some plug-ins implement several types) and the modifier defines how success or failure of the plugin is handled. The configured plugins are then combined into two stacks. The first is processed each time a authentication decision has to be made and the second stack is used to perform mapping and reverse mapping. The first stack consists of auth, map, account and session plugins, the second one only of identity plugins.

auth|map|account|session|identity optional|required|requisite|sufficient plug-in ["key=value" ...]

auth plug-ins are used to read the users public and private credentials and ask some authority, if those are valid for accessing the system.

map plug-ins map the user information obtained in the auth step to UID and GIDs. This may also be done in several steps (e.g., the vorolemap plug-in maps the users DN +FQAN to a username which is then mapped to UID/GIDs by the authzdb plug-in.

account plug-ins verify the validity of a possibly mapped identity of the user and may reject the login depending on information gathered within the map step.

session plug-ins usually enrich the session with additional attributes like the user’s home directory.

identity plug-ins have have two functions to map from usernames to UID and GID and vice versa.

The meaning of the modifiers follow the PAM specification:

optional The success or failure of this plug-in is only important if it is the only plug-in in the stack associated with this type.

sufficient Success of such a plug-in is enough to satisfy the authentication requirements of the stack of plug-ins (if a prior required plug-in has failed the success of this one is ignored). A failure of this plug-in is not deemed as fatal for the login attempt. If the plug-in succeeds gPlazma2 immediately proceeds with the next plug-in type or returns control to the door if this was the last stack.

required Failure of such a plug-in will ultimately lead to gPlazma2 returning failure but only after the remaining plug-ins for this type have been invoked.

requisite Like required, however, in the case that such a plug-in returns a failure, control is directly returned to the door.

plug-ins
gPlazma2 functionality is configured by combining different types of plug-ins to work together in a way that matches your requirements. For this purpose there are four different types of plug-ins. These types correspond to the keywords auth, map, account, session and identity from the previous section.
Authorization in dCache

authzdb

The authzdb plug-in implementation offers map and session functionality. As a map-plug-in it takes a username and maps it to UID/GID using the storage-authzdb file.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>authzdb</td>
<td>Path to storage-authzdb</td>
<td>/etc/grid-security/storage-authzdb</td>
</tr>
</tbody>
</table>

argus

The argus plug-in is an account plug-in, currently used for banning users by their DN. It talks to your site’s ARGUS system (see [https://twiki.cern.ch/twiki/bin/view/EGEE/AuthorizationFramework](https://twiki.cern.ch/twiki/bin/view/EGEE/AuthorizationFramework)) to check for banned users.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostCert</td>
<td>Path to host certificate</td>
<td>/etc/grid-security/hostcert.pem</td>
</tr>
<tr>

</tr>
<tr>
<td>PEPEndpoint</td>
<td>URL of PEP service</td>
<td><a href="https://localhost:8154/authz">https://localhost:8154/authz</a></td>
</tr>
</tbody>
</table>

GridMap

The gridmap plug-in is a mapping plug-in. It maps GLOBUS identities and Kerberos identities to a username.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gridmap</td>
<td>Path to grid-mapfile</td>
<td>/etc/grid-security/grid-mapfile</td>
</tr>
</tbody>
</table>

kpwd

The kpwd plug-in has auth, map and session capabilities. It authorizes users by username and password, by pairs of DN and FQAN and by Kerberos principals. As a map-plug-in it maps usernames to UID and GID. And as a session plug-in it adds root and home path information to the session based on the user’s username.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwdfile</td>
<td>Path to dcache.kpwd</td>
<td>/etc/dcache/dcache.kpwd</td>
</tr>
</tbody>
</table>

voms

The voms plug-in is a auth plug-in. It can be used to verify X.509 certificates. It takes the certificates and checks their validity by testing them against the trusted CAs. The verified certificates are then stored and passed on to the other plug-ins in the stack.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>

<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>vomsdir</td>
<td>Path to vomsdir</td>
<td>/etc/grid-security/vomsdir</td>
</tr>
</tbody>
</table>

**vorolemap**

The `voms` plug-in is a map plug-in. It can be used to map pairs of DN and FQAN to a username via a vorolemap file.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>vorolemap</td>
<td>Path to grid-vorolemap</td>
<td>/etc/grid-security/grid-vorolemap</td>
</tr>
</tbody>
</table>

**X.509 plug-in**

The X.509 plug-in is an auth plug-in that extracts X.509 certificate chains from the credentials of a user to be used by other plug-ins.

**Using X.509 Certificates**

Most plug-ins of gPlazma support X.509 certificates for authentication and authorisation. X.509 certificates are used to identify entities (e.g., persons, hosts) in the Internet. The certificates contain a DN (Distinguished Name) that uniquely describes the entity. To give the certificate credibility it is issued by a CA (Certificate Authority) which checks the identity upon request of the certificate (e.g., by checking the persons id). For the use of X.509 certificates with dCache your users will have to request a certificate from a CA you trust and you need host certificates for every host of your dCache instance.

**CA Certificates**

To be able to locally verify the validity of the certificates, you need to store the CA certificates on your system. Most operating systems come with a number of commercial CA certificates, but for the Grid you will need the certificates of the Grid CAs. For this, CERN packages a number of CA certificates. These are deployed by most grid sites. By deploying these certificates, you state that you trust the CA’s procedure for the identification of individuals and you agree to act promptly if there are any security issues.

To install the CERN CA certificates follow the following steps:

```
[root] # cd /etc/yum.repos.d/
[root] # yum install lcg-CA
```

This will create the directory `/etc/grid-security/certificates` which contains the Grid CA certificates.

Certificates which have been revoked are collected in certificate revocation lists (CRLs). To get the CRLs install the `fetch-crl` command as described below.

```
[root] # yum install fetch-crl
[root] # /usr/sbin/fetch-crl
```

`fetch-crl` adds X.509 CRLs to `/etc/grid-security/certificates`. It is recommended to set up a cron job to periodically update the CRLs.
Authorization in dCache

User Certificate

If you do not have a valid grid user certificate yet, you have to request one from your CA. Follow the instructions from your CA on how to get a certificate. After your request was accepted you will get a URL pointing to your new certificate. Install it into your browser to be able to access grid resources with it. Once you have the certificate in your browser, make a backup and name it `userCertificate.p12`. Copy the user certificate to the directory `~/.globus/` on your worker node and convert it to `usercert.pem` and `userkey.pem` as described below.

```
[user] $ openssl pkcs12 -clcerts -nokeys -in userCertificate.p12 -out usercert.pem
Enter Import Password:
MAC verified OK
```

During the backup your browser asked you for a password to encrypt the certificate. Enter this password here when asked for a password. This will create your user certificate.

```
[user] $ openssl pkcs12 -nocerts -in userCertificate.p12 -out userkey.pem
Enter Import Password:
MAC verified OK
Enter PEM pass phrase:
```

In this step you need to again enter the backup password. When asked for the PEM pass phrase choose a secure password. If you want to use your key without having to type in the pass phrase every time, you can remove it by executing the following command.

```
[root] # openssl rsa -in userkey.pem -out userkey.pem
Enter pass phrase for userkey.pem:
writing RSA key
```

Now change the file permissions to make the key only readable by you and the certificate world readable and only writable by you.

```
[root] # chmod 400 userkey.pem
[root] # chmod 644 usercert.pem
```

Host Certificate

To request a host certificate for your server host, follow again the instructions of your CA.

The conversion to `hostcert.pem` and `hostkey.pem` works analogous to the user certificate. For the hostkey you have to remove the pass phrase. How to do this is also explained in the previous section. Finally copy the `host*.*.pem` files to `/etc/grid-security/` as root and change the file permissions in favour of the user running the grid application.

VOMS Proxy Certificate

For very large groups of people, it is often more convenient to authorise people based on their membership of some group. To identify that they are a member of some group, the certificate owner can create a new short-lived X.509 certificate that includes their membership of various groups. This short-lived certificate is called a proxy-certificate and, if the membership information comes from a VOMS server, it is often referred to as a VOMS-proxy.

```
[root] # cd /etc/yum.repos.d/
```
Authorization in dCache

Creating a VOMS proxy

To create a VOMS proxy for your user certificate you need to execute the `voms-proxy-init` as a user.

```
[user] $ export PATH=/opt/glite/bin/:$PATH
[user] $ voms-proxy-init
Enter GRID pass phrase:
Your identity: /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
Creating proxy ............................................................Done
Your proxy is valid until Mon Mar  7 22:06:15 2011
```

Certifying your membership of a VO

You can certify your membership of a VO by using the command `voms-proxy-init -voms yourVO`. This is useful as in dCache authorization can be done by VO (see the section called “Authorizing a VO”). To be able to use the extension `-voms yourVO` you need to be able to access VOMS servers. To this end you need the the VOMS server’s and the CA’s DN. Create a file `/etc/grid-security/vomsdir/VO/hostname.lsc` per VOMS server containing on the 1st line the VOMS server’s DN and on the 2nd line, the corresponding CA’s DN. The name of this file should be the fully qualified hostname followed by an `.lsc` extension and the file must appear in a subdirectory `/etc/grid-security/vomsdir/VO` for each VO that is supported by that VOMS server and by the site.

At [http://operations-portal.egi.eu/vo](http://operations-portal.egi.eu/vo) you can search for a VO and find this information.

For example, the file `/etc/grid-security/vomsdir/desy/grid-voms.desy.de.lsc` contains:

```
/C=DE/O=GermanGrid/OU=DESY/CN=host/grid-voms.desy.de
/C=DE/O=GermanGrid/CN=GridKa-CA
```

where the first entry is the DN of the DESY VOMS server and the second entry is the DN of the CA which signed the DESY VOMS server’s certificate.

In addition, you need to have a file `/opt/glite/etc/vomses` containing your VO’s VOMS server.

For DESY the file `/opt/glite/etc/vomses` should contain the entry

```
"desy" "grid-voms.desy.de" "15104" "/C=DE/O=GermanGrid/OU=DESY/CN=host/grid-voms.desy.de" "desy" "24"
```

The first entry “desy” is the real name or a nickname of your VO. “grid-voms.desy.de” is the hostname of the VOMS server. The number “15104” is the port number the server is listening on. The forth entry is the DN of the server’s VOMS certificate. The fifth entry, “desy”, is the VO name and the last entry is the globus version number which is not used anymore and can be omitted.

Use the command `voms-proxy-init -voms` to create a VOMS proxy with VO “desy”.

```
[user] $ voms-proxy-init -voms desy
Enter GRID pass phrase:
Your identity: /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
Creating temporary proxy .............................................. Done
Contacting grid-voms.desy.de:15104 [/C=DE/O=GermanGrid/OU=DESY/CN=host/grid-voms.desy.de] "desy" Done
Creating proxy ......................................................... Done
Your proxy is valid until Mon Mar  7 23:52:13 2011
```
Authorization in dCache

View the information about your VOMS proxy with `voms-proxy-info`

```
[user] $ voms-proxy-info
subject   : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe/CN=proxy
issuer    : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
identity  : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
 type     : proxy
 strength  : 1024 bits
path      : /tmp/x509up_u500
timeleft  : 11:28:02
```

The last line tells you how much longer your proxy will be valid.

If your proxy is expired you will get

```
[user] $ voms-proxy-info
subject   : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe/CN=proxy
issuer    : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
identity  : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
 type     : proxy
 strength  : 1024 bits
path      : /tmp/x509up_u500
timeleft  : 0:00:00
```

The command `voms-proxy-info -all` gives you information about the proxy and about the VO.

```
[user] $ voms-proxy-info -all
subject   : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe/CN=proxy
issuer    : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
identity  : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
 type     : proxy
 strength  : 1024 bits
path      : /tmp/x509up_u500
timeleft  : 11:24:57
=== VO desy extension information ===
VO        : desy
subject   : /C=DE/O=GermanGrid/OU=DESY/CN=John Doe
issuer    : /C=DE/O=GermanGrid/OU=DESY/CN=host/grid-voms.desy.de
attribute : /desy/Role=NULL/Capability=NULL
attribute : /desy/test/Role=NULL/Capability=NULL
timeleft  : 11:24:57
uri       : grid-voms.desy.de:15104
```

Use the command `voms-proxy-destroy` to destroy your VOMS proxy.

```
[user] $ voms-proxy-destroy
[user] $ voms-proxy-info
Couldn't find a valid proxy.
```

Configuration files

In this section we explain the format of the different files that are used by both gPlazma1 and gPlazma2 plug-ins.

**storage-authzdb**

In gPlazma, except for the kpwd plug-in, authorization is a two-step process. First, a username is obtained from a mapping of the user’s DN or his DN and role, then a mapping of username to UID and GID with optional additional session parameters like the root path is performed. For the second mapping usually the file called `storage-authzdb` is used.
Authorization in dCache

Preparing storage-authzdb

The default location of the storage-authzdb is /etc/grid-security. Before the mapping entries there has to be a line specifying the version of the used file format.

```
version 2.1
```

dCache supports versions 2.1 and to some extend 2.2.

Except for empty lines and comments (lines start with #) the configuration lines have the following format:

```
authorize username (read-only|read-write) UID GID[,GID]* homedir rootdir
```

For legacy reasons there may be a third path entry which is ignored by dCache. The username here has to be the name the user has been mapped to in the first step (e.g., by his DN).

```
authorize john read-write 1001 100 / /data/experiments /
```

In this example user john will be mapped to UID 1001 and GID 100 with read access on the directory /data/experiments. You may choose to set the user’s root directory to /.

```
authorize adm read-write 1000 100 / / /
```

In this case the user adm will be granted read/write access in any path, given that the file system permissions in Chimera also allow the transfer.

The first path is nearly always left as “/”, but it may be used as a home directory in interactive session, as a subdirectory of the root path. Upon login, the second path is used as the user’s root, and a “cd” is performed to the first path. The first path is always defined as being relative to the second path.

Multiple GIDs can be assigned by using comma-separated values for the GID file, as in

```
authorize john read-write 1001 100,101,200 / / /
```

The lines of the storage-authzdb file are similar to the “login” lines of the dcache.kpwd file. If you already have a dcache.kpwd file, you can easily create storage-authzdb by taking the lines from your dcache.kpwd file that start with the word login, for example,

```
login john read-write 1001 100 / /data/experiments /
```

and replace the word login with authorize. The following line does this for you.

```
[root] # sed "s/^ *login/authorize/" dcache.kpwd|grep "^authorize" > storage-authzdb
```

The gplazmalite-vorole-mapping plug-in

The gPlazma policy file /etc/dcache/dcachesrm-gplazma.policy contains two lines for this plug-in.
Authorization in dCache

# Built-in gPLAZMAlite grid VO role mapping
gridVoRolemapPath="/etc/grid-security/grid-vorolemap"
gridVoRoleStorageAuthzPath="/etc/grid-security/storage-authzdb"

The second is the storage-authzdb used in other plug-ins. See the above documentation on storage-authzdb for how to create the file.

## Preparing grid-vorolemap

The file is similar in format to the grid-mapfile, however there is an additional field following the DN (Certificate Subject), containing the FQAN (Fully Qualified Attribute Name).

```
/C=DE/O=GermanGrid/OU=DESY/CN=John Doe* /some-vo* doegroup
/C=DE/DC=GermanGrid/O=DESY/CN=John Doe* /some-vo/Role=NULL* doegroup
/C=DE/DC=GermanGrid/O=DESY/CN=John Doe* /some-vo/Role=NULL/Capability=NULL doegroup
```

Therefore each line has three fields: the user’s DN, the user’s FQAN, and the username that the DN and FQAN combination are to be mapped to.

The FQAN is sometimes semantically referred to as the “role”. The same user can be mapped to different usernames depending on what their FQAN is. The FQAN is determined by how the user creates their proxy, for example, using `voms-proxy-init`. The FQAN contains the user’s Group, Role (optional), and Capability (optional). The latter two may be set to the string “NULL”, in which case they will be ignored by the plug-in. Therefore the three lines in the example above are equivalent.

If a user is authorized in multiple roles, for example

```
/DC=org/DC=doegrids/OU=People/CN=John Doe* /some-vo/sub-grp* vo_sub_grp_user
/DC=org/DC=doegrids/OU=People/CN=John Doe* /some-vo/sub-grp/Role=user* vouser
/DC=org/DC=doegrids/OU=People/CN=John Doe* /some-vo/sub-grp/Role=admin* voadmin
/DC=org/DC=doegrids/OU=People/CN=John Doe* /some-vo/sub-grp/Role=prod* voprod
```

he will get the username corresponding to the FQAN found in the proxy that the user creates for use by the client software. If the user actually creates several roles in his proxy, authorization (and subsequent check of path and file system permissions) will be attempted for each role in the order that they are found in the proxy.

In a GridFTP URL, the user may also explicitly request a username.

```
gsiftp://doeprod@ftp-door.example.org:2811/testfile1
```

in which case other roles will be disregarded.

## Authorizing a VO

Instead of individual DNs, it is allowed to use * or "*" as the first field, such as

```
** */desy/Role=production/* desyprod
```

In that case, any DN with the corresponding role will match. It should be noted that a match is first attempted with the explicit DN. Therefore if both DN and "*" matches can be made, the DN match will take precedence. This is true for the revocation matches as well (see below).
Thus a user with subject /C=DE/O=GermanGrid/OU=DESY/CN=John Doe and role /desy/Role=production will be mapped to username desyprod via the above storage-authzdb line with "**" for the DN, except if there is also a line such as

```
"/C=DE/O=GermanGrid/OU=DESY/CN=John Doe"
"/desy/Role=production" desyprod2
```

in which case the username will be desyprod2.

**Revocation Entries**

To create a revocation entry, add a line with a dash (--) as the username, such as

```
"/C=DE/O=GermanGrid/OU=DESY/CN=John Doe" "/desy/production" --
```

or modify the username of the entry if it already exists. The behaviour is undefined if there are two entries which differ only by username.

Since DN is matched first, if a user would be authorized by his VO membership through a "**" entry, but is matched according to his DN to a revocation entry, authorization would be denied. Likewise if a whole VO were denied in a revocation entry, but some user in that VO could be mapped to a username through his DN, then authorization would be granted.

**More Examples**

Suppose that there are users in production roles that are expected to write into the storage system data which will be read by other users. In that case, to protect the data the non-production users would be given read-only access. Here in /etc/grid-security/grid-vorolemap the production role maps to username cmsprod, and the role which reads the data maps to cmsuser.

```
"**" "/cms/uscms/Role=cmsprod" cmsprod
"**" "/cms/uscms/Role=cmsuser" cmsuser
```

The read-write privilege is controlled by the third field in the lines of /etc/grid-security/storage-authzdb

```
authorize cmsprod read-write 9811 5063 /data/authorize cmsuser read-only 10001 6800 /data/
```

Another use case is when users are to have their own directories within the storage system. This can be arranged within the gPlazma configuration files by mapping each user’s DN to a unique username and then mapping each username to a unique root path. As an example, lines from /etc/grid-security/grid-vorolemap would therefore be written

```
"/DC=org/DC=doegrids/OU=People/CN=Selby Booth" "/cms" cms821
"/DC=org/DC=doegrids/OU=People/CN=Kenja Kassi" "/cms" cms822
"/DC=org/DC=doegrids/OU=People/CN=Ameil Fauss" "/cms" cms823
```

and the corresponding lines from /etc/grid-security/storage-authzdb would be

```
authorize cms821 read-write 10821 7000 /data/cms821/authorize cms822 read-write 10822 7000 /data/cms822/authorize cms823 read-write 10823 7000 /data/cms823/
```
The kpwd plug-in

The section in the gPlazma policy file for the kpwd plug-in specifies the location of the dcache.kpwd file, for example:

```yaml
# dcache.kpwd
kpwdPath="/etc/dcache/dcache.kpwd"
```

To maintain only one such file, make sure that this is the same location as defined in `/usr/share/dcache/defaults/dcache.properties`.

Use `/usr/share/dcache/examples/gplazma/dcache.kpwd` to create this file.

The grid-mapfile plug-in

Two file locations are defined in the policy file for this plug-in:

```yaml
# grid-mapfile
gridMapFilePath="/etc/grid-security/grid-mapfile"
storageAuthzPath="/etc/grid-security/storage-authzdb"
```

Preparing the grid-mapfile

The grid-mapfile is the same as that used in other applications. It can be created in various ways, either by connecting directly to VOMS or GUMS servers, or by hand.

Each line contains two fields: a DN (Certificate Subject) in quotes, and the username it is to be mapped to.

```
"/C=DE/O=GermanGrid/OU=DESY/CN=John Doe" johndoe
```

When using the grid-mapfile plug-in, the storage-authzdb file must also be configured. See the section called "storage-authzdb" for details.

The saml-vo-mapping plug-in

There are two lines in the policy file for this plug-in.

```yaml
# SAML-based grid VO role mapping
mappingServiceUrl="https://gums.oursite.edu:8443/gums/services/GUMSAuthorizationServicePort"
# Time in seconds to cache the mapping in memory
saml-vo-mapping-cache-lifetime="60"
```

The first line contains the URL for the GUMS web service. Replace the URL with that of the site-specific GUMS. When using the `GUMSAuthorizationServicePort`, the service will only provide the username mapping and it will still be necessary to have the storage-authzdb file used in other plug-ins. See the above documentation storage-authzdb for how to create the file. If a GUMS server providing a `StorageAuthorizationServicePort` with correct UID, GID, and root path information for your site is available, the storage-authzdb file is not necessary.

The second line contains the value of the caching lifetime. In order to decrease the volume of requests to the SAML authorization (GUMS) service, authorizations for the saml-vo-mapping plug-in are
by default cached for a period of time. To change the caching duration, modify the `saml-vo-mapping-cache-lifetime` value in `/etc/dcache/dcachesrm-gplazma.policy`.

```bash
saml-vo-mapping-cache-lifetime="120"
```

To turn off caching, set the value to 0. The default value is 180 seconds.

### The xacml-vo-mapping plug-in

GPlazma includes an authorization plug-in, to support the XACML authorization schema. Using XACML with SOAP messaging allows GPlazma to acquire authorization mappings from any service which supports the obligation profile for grid interoperability [http://cd-docdb.fnal.gov/cgi-bin/ShowDocument?docid=2952]. Servers presently supporting XACML mapping are the latest releases of GUMS and SCAS. Using the new plug-in is optional, and previous configuration files are still compatible with GPlazma. It is normally not necessary to change this file, but if you have customized the previous copy, transfer your changes to the new batch file.

The configuration is very similar to that for the `saml-vo-mapping` plug-in. There are two lines for the configuration.

```bash
# XACML-based grid VO role mapping
XACMlmappingServiceUrl=https://gums.example.org:8443/gums/services/GUMS;
XACMlAuthorizationServicePort="8443"
# Time in seconds to cache the mapping in memory
xacml-vo-mapping-cache-lifetime="180"
```

```bash
# XACML-based grid VO role mapping
XACMlmappingServiceUrl=https://scas.europeansite.eu:8443
# Time in seconds to cache the mapping in memory
xacml-vo-mapping-cache-lifetime="180"
```

As for the `saml-vo-mapping` plug-in, the first line contains the URL for the web service. Replace the URL with that of the site-specific GUMS or SCAS server. When using the GUMSXACMLAuthorizationServicePort (notice the difference in service name from that for the `saml-vo-mapping` plug-in) with a GUMS server, the service will only provide the username mapping and it will still be necessary to have the storage-authzdb file used in other plug-ins. See the above documentation about storage-authzdb for how to create the file. An SCAS server will return a UID, a primary GID, and secondary GIDs, but not a root path. A storage-authzdb file will be necessary to assign the root path. Since SCAS does not return a username, the convention in GPlazma is to use uid:gid for the username, where uid is the string representation of the UID returned by SCAS, and gid is the string representation of the primary GID returned by SCAS. Thus a line such as

```bash
authorize 13160:9767 read-write 13160 9767 /data /
```

in `/etc/grid-security/storage-authzdb` will serve to assign the user mapped by SCAS to UID=13160 and primary GID=9767 the root path `/data`. It is best for consistency’s sake to fill in the UID and GID fields with the same values as in the uid:gid field. Additional secondary GIDs can be assigned by using comma-separated values in the GID field. Any GIDs there not already returned as secondary GIDs by SCAS will be added to the secondary GIDs list.

The second line contains the value of the caching lifetime. In order to decrease the volume of requests to the XACML authorization (GUMS or SCAS) service, authorizations for the `saml-vo-mapping` plug-in method are by default cached for a period of time. To change the caching duration, modify the `xacml-vo-mapping-cache-lifetime` value in `/etc/dcache/dcachesrm-gplazma.policy`.

```bash
authorize 13160:9767 read-write 13160 9767 /data /
```
Authorization in dCache

saml-vo-mapping-cache-lifetime="120"

To turn off caching, set the value to 0. For the xacml-vo-mapping plug-in the default value is 180 seconds.

**gPlazma specific dCache configuration**

dCache has many parameters that can be used to configure the systems behaviour. You can find all these parameters well documented and together with their default values in the properties files in /usr/share/dcache/defaults/. To use non-default values, you have to set the new values in /etc/dcache/dcache.conf or in the layout file. Do not change the defaults in the properties files! After changing a parameter you have to restart the concerned cells.

Refer to the file gPlazma.properties for a full list of properties for gPlazma The following table shows the most commonly used ones:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>gPlazmaNumberOfSimultaneousRequests</td>
<td>The number of concurrent requests</td>
<td>30</td>
</tr>
<tr>
<td>useGPlazmaAuthorization-Module</td>
<td>Run gPlazma local for each door</td>
<td>False</td>
</tr>
<tr>
<td>useGPlazmaAuthorization-Cell</td>
<td>Run a central gPlazma instance.</td>
<td>True</td>
</tr>
</tbody>
</table>

Setting the value for gPlazmaNumberOfSimultaneousRequests too high may result in large spikes of CPU activity and the potential to run out of memory. Setting the number too low results in potentially slow login activity.

The default mode for gPlazma is to run centralised in one instance. It is however possible to specify to use gPlazma1 as module running locally to the doors. Set this property to True in the domain you wish to run the module in.

If you decide to run gPlazma1 as a module you can switch off the centralised by setting useGPlazmaAuthorizationCell to False. Note that is also possible to mix both modes.

**Using Direct Calls of gPlazma1 Methods**

Cells may also call gPlazma1 methods as an alternative, or as a fall-back, to using the gPlazma cell.

**Operation without a gPlazma Cell**

If the gPlazma cell is not started, other cells can still authorize by calling gPlazma1 methods directly from a pluggable module. The gPlazma1 control files and host certificates are needed on the node from which authorization will take place. To invoke the gPlazma1 modules, modify the following line in gridftpdoorSetup or srmSetup to

```plaintext
useGPlazmaAuthorizationModule=true
```

and make sure that the gPlazmaPolicy line defines a valid gPlazma1 policy file on the node for which authorization is to occur:
Authorization in dCache

No adjustable timeout is available, but any blocking would likely be due to a socket read in the saml-vo-mapping plug-in, which is circumvented by a built-in 30-second timeout.

Using a gPlazma Cell with a Direct-Call Fallback

Both a call to the gPlazma cell and the direct call of the gPlazmal module may be specified. In that case, authentication will first be tried via the gPlazma cell, and if that does not succeed, authentication by direct invocation of gPlazmal methods will be tried. Modify the following lines to:

```plaintext
useGPlazmaAuthorizationModule=true
useGPlazmaAuthorizationCell=true
```

Make sure that the line for `gplazmaPolicy` set to a local policy file on the node. The gPlazma policy file on the GridFTP door or srm does not have to specify the same plug-ins as the gPlazma cell.

gPlazma config example to work with authenticated webadmin

In this section an example configuration of gPlazmal is presented to enable working with Webadmin in authenticated mode and give a user administrator access.

The `/etc/dcache/dcachesrm-gplazma.policy` file would look like this:

```plaintext
# Switches
xacml-vo-mapping="OFF"
saml-vo-mapping="OFF"
kpwd="ON"
grid-mapfile="OFF"
gplazmalite-vorole-mapping="OFF"

# Priorities
xacml-vo-mapping-priority="5"
saml-vo-mapping-priority="1"
kpwd-priority="3"
grid-mapfile-priority="4"
gplazmalite-vorole-mapping-priority="2"

# Configurable Options for plug-ins|Services
# #################################################################################
# Path to local or remotely accessible authorization repositories|services.
# A valid path is required if corresponding switch is ON.
# dcache.kpwd
kpwdPath="/etc/dcache/dcache.kpwd"
# #################################################################################
# END

The /etc/dcache/dcache.kpwd file would look like this:

```plaintext
version 2.1
```
Authorization in dCache

Mapping "/C=DE/O=ExampleOrganisation/OU=EXAMPLE/CN=John Doe" john

# the following are the user auth records
login jans read-write 1000 100 / / /
/C=DE/O=ExampleOrganisation/OU=EXAMPLE/CN=John Doe

# set pwd
passwd john 8402480 read-write 1000 100 / / /

This maps the subject part of a Grid-Certificate subject=/C=DE/O=ExampleOrganisation/
OU=EXAMPLE/CN=John Doe to the User john and the entry

login john read-write 1000 100 / / /
/C=DE/O=GermanGrid/OU=DESY/CN=John Doe

applies unix-like values to john, most important is the 100, because it is the assigned GID. This must
match the value of the webadminAdminGid configured in your webadmin. This is sufficient for login
using a certificate. The entry

passwd john 8402480 read-write 1000 100 / / /

enables Username/Password login, such as a valid login would be user john with some password. The
password is encrypted with the kpwd-algorithm (also see the section called “The kpwd plug-in”) and
then stored in the file. Again the 100 here is the assigned GID.
Chapter 13. dCache as xRootd-Server

This chapter explains how to configure dCache in order to access it via the xrootd protocol, allowing xrootd-Clients like ROOT’s TXNetfile and xrdf to do file operations against a dCache instance in a transparent manner. dCache implements version 2.1.6 of xrootd protocol.

Setting up

To allow file transfers in and out of dCache using xrootd, a new xrootd door must be started. This door acts then as the entry point to all xrootd requests. Compared to the native xrootd server-implementation (produced by SLAC), the xrootd door corresponds to the redirector node.

To enable the xrootd door, you have to change the layout file corresponding to your dCache-instance. Enable the xrootd-service within the domain that you want to run it by adding the following line

```
[domainName/xrootd]
```

You can just add the following lines to the layout file:

```
[xrootd-@${host.name}Domain]
[xrootd-@${host.name}Domain/xrootd]
```

After a restart of the domain running the xrootd door, done e.g. by executing

```
[root] # ${dCacheHome}/bin/dcache restart xrootd-babelfishDomain
Stopping xrootd-babelfishDomain (pid=30246) 0 1 2 3 4 5 6 7 done
Starting xrootd-babelfishDomain done
```

the xrootd door should be running. A few minutes later it should appear at the web monitoring interface under "Cell Services" (see the section called “The Web Interface for Monitoring dCache”).

Parameters

The default port the xrootd door is listening on is 1094. This can be changed two ways:

1. Per door: Edit your instance’s layout file, for example /etc/dcache/lay-outs/example.conf and add the desired port for the xrootd door in a separate line (a restart of the domain(s) running the xrootd door is required):

```
[xrootd-@${host.name}Domain]
[xrootd-@${host.name}Domain/xrootd]
port = 1095
```

2. Globally: Edit /etc/dcache/dcache.conf and add the variable xrootdPort with the desired value (a restart of the domain(s) running the xrootd door is required):

```
```
dCache as xRootd-Server

```
xrootdPort=1095
```

For controlling the TCP-portrange within which xrootd-movers will start listening in the poolDo-
main, you can add the properties net.lan.port.min and net.lan.port.max to /etc/ dcacce/dcache.conf and adapt them according to your preferences. The default values can be viewed in /usr/share/dcache/defaults/dcache.properties.

```
.. net.lan.port.min=30100
net.lan.port.max=30200
..```

Quick tests

The subsequent paragraphs describe a quick guide on how to test xrootd using the xrdcp and ROOT clients.

Copying files with xrdcp

A simple way to get files in and out of dCache via xrootd is the command xrdcp. It is included in every xrootd and ROOT distribution.

To transfer a single file in and out of dCache, just issue

```
[user] $ xrdcp /bin/sh root://xrootd-door.example.org/pnfs/example.org/data/xrd_test
[user] $ xrdcp root://xrootd-door.example.org/pnfs/example.org/data/xrd_test /dev/null
```

Accessing files from within ROOT

This simple ROOT example shows how to write a randomly filled histogram to a file in dCache:

```
root [0] TH1F h("testhisto", "test", 100, -4, 4);
root [1] h->FillRandom("gaus", 10000);
061024 12:03:52 001 Xrd: Create: (C) 2004 SLAC INFN XrdClient 0.3
root [3] h->Write();
root [4] f->Write();
root [5] f->Close();
061101 15:57:42 14991 Xrd: XrdClientMessage::ReadRaw: Error reading header (8 bytes)
```

Closing remote xrootd files that live in dCache produces this warning, but has absolutely no effect on subsequent ROOT commands. It happens because dCache closes all TCP connections after finishing a file transfer, while xrootd expects to keep them open for later reuse.

To read it back into ROOT from dCache:

```
root [8] reopen->ls();
TXNetFile* //pnfs/example.org/data/test.root
TXNetFile* //pnfs/example.org/data/test.root
KEY: TH1F testhisto;1 test
```
dCache as xRootd-Server

**xrootd security**

**Read-Write access**

Per default dCache xrootd is restricted to read-only, because plain xrootd is completely unauthenticated. A typical error message on the clientside if the server is read-only looks like:

```
[user] $ xrdcp -d 1 /bin/sh root://ford.desy.de//pnfs/desy.de/data/xrd_test2
Setting debug level 1
061024 18:43:05 001 Xrd: main: (C) 2004 SLAC INFN xrdcp 0.2 beta
061024 18:43:05 001 Xrd: Create: (C) 2004 SLAC INFN XrdClient kXR_ver002+kXR_asyncap
061024 18:43:05 001 Xrd: ShowUrls: The converted URLs count is 1
061024 18:43:05 001 Xrd: Open: Opening the remote file /pnfs/desy.de/data/asdfas
061024 18:43:05 001 XrdClient::TryOpen: doitparallel=1
061024 18:43:06 5819 Xrd: SendGenCommand: Server declared: Permission denied. Access is read only. (error code: 3003)
Error accessing path/file for root://ford//pnfs/desy.de/data/asdfas
```

To enable read-write access, add the following line to `${dCacheHome}/etc/dcache.conf`

```
.. xrootdIsReadOnly=false
.. and restart any domain(s) running a xrootd door.
```

Please note that due to the unauthenticated nature of this access mode, files can be written and read to/from any subdirectory in the pnfs namespace (including the automatic creation of parent directories). If there is no user information at the time of request, new files/subdirectories generated through xrootd will inherit UID/GID from its parent directory. The user used for this can be configured via the xrootdUser property.

**Permitting read/write access on selected directories**

To overcome the security issue of uncontrolled xrootd read and write access mentioned in the previous section, it is possible to restrict read and write access on a per-directory basis (including subdirectories).

To activate this feature, a colon-separated list containing the full paths of authorized directories must be added to `/etc/dcache/dcache.conf`. If both read and write access should be authorized for certain directories, add the following line to `/etc/dcache/dcache.conf`:

```
.. xrootdAllowedPaths=/pnfs/example.org/path1:/pnfs/example.org/path2
.. If you want to split permissions depending on whether the operation is reading or writing, add the following lines instead:
```

```
.. xrootdAllowedReadPaths=/pnfs/example.org/rpath1:/pnfs/example.org/rpath2
```
A restart of the `xrootd` door is required to make the changes take effect. As soon as any of the above properties are set, all read or write requests to directories not matching the allowed path lists will be refused. Symlinks are however not restricted to these prefixes.

## Token-based authorization

The first thing to do is to setup the keystore. The keystore file basically specifies all RSA-keypairs used within the authorization process and has exactly the same syntax as in the native `xrootd` tokenauthorization implementation. In this file, each line beginning with the keyword `KEY` corresponds to a certain Virtual Organisation (VO) and specifies the remote public (owned by the file catalogue) and the local private key belonging to that VO. A line containing the statement `"KEY VO:*"` defines a default keypair that is used as a fallback solution if no VO is specified in token-enhanced `xrootd` requests. Lines not starting with the `KEY` keyword are ignored. A template can be found in `/usr/share/dcache/examples/xrootd/keystore`.

The keys itself have to be converted into a certain format in order to be loaded into the authorization plugin. dCache expects both keys to be binary DER-encoded (Distinguished Encoding Rules for ASN.1). Furthermore the private key must be PKCS #8-compliant and the public key must follow the X.509-standard.

The following example demonstrates how to create and convert a keypair using OpenSSL:

```bash
Generate new RSA private key
[root] # openssl genrsa -rand 12938467 -out key.pem 1024

Create certificate request
[root] # openssl req -new -inform PEM -key key.pem -outform PEM -out certreq.pem

Create certificate by self-signing certificate request
[root] # openssl x509 -days 3650 -signkey key.pem -in certreq.pem -req -out cert.pem

Extract public key from certificate
[root] # openssl x509 -pubkey -in cert.pem -out pkey.pem
[root] # openssl pkcs8 -in key.pem -topk8 -nocrypt -outform DER -out new_private_key
[root] # openssl enc -base64 -d -in pkey.pem -out new_public_key

Only the last two lines are performing the actual conversion, therefore you can skip the previous lines in case you already have a keypair. Make sure that your keystore file correctly points to the converted keys.

To enable the plugin, it is necessary to add the following two lines to the file `/etc/dcache/dcache.conf`, so that it looks like

```bash
.. 
xrootdAllowedWritePaths=/pnfs/example.org/wpath1:/pnfs/example.org/wpath2
.. XRootDDoor=

xrootdAuthzPlugin=org.dcache.xrootd.security.plugins.tokenauthz.TokenAuthorizationFactory
xrootdAuthzKeystore=Path_to_your_Keystore
.. 
```

After doing a restart of dCache, any requests without an appropriate token should result in an error saying "authorization check failed: No authorization token found in open request, access denied.(error code: 3010)".
If both token-based authorization and read-only access are activated, the read-only restriction will dominate (local settings have precedence over remote file catalogue permissions).

**Strong authentication**

The xrootd-implementation in dCache includes a pluggable authentication framework. To control which authentication mechanism is used by xrootd, add the `xrootdAuthNPlugin` option to your dCache configuration and set it to the desired value.

For instance, to enable GSI authentication in xrootd, add the following line to `/etc/dcache/dcache.conf`:

```bash
.. xrootdAuthNPlugin=gsi ..
```

When using GSI authentication, depending on your setup, you may or may not want dCache to fail if the host certificate chain cannot be verified against trusted certificate authorities. Whether dCache performs this check can be controlled by setting the option `verifyHostCertificateChain`:

```bash
.. verifyHostCertificateChain=true ..
```

Authorization of the user information obtained by strong authentication is performed by contacting the gPlazma service. Please refer to Chapter 12, *Authorization in dCache* for instructions about how to configure gPlazma.

**Security consideration**

In general GSI on xrootd is not secure. It does not provide confidentiality and integrity guarantees and hence does not protect against man-in-the-middle attacks.

**Precedence of security mechanisms**

The previously explained methods to restrict access via xrootd can also be used together. The precedence applied in that case is as following:

**Note**

The xrootd-door can be configured to use either token authorization or strong authentication with gPlazma authorization. A combination of both is currently not possible.

The permission check executed by the authorization plugin (if one is installed) is given the lowest priority, because it can be controlled by a remote party. E.g. in the case of token-based authorization, access control is determined by the file catalogue (global namespace).

The same argument holds for many strong authentication mechanisms - for example, both the GSI protocol as well as the Kerberos protocols require trust in remote authorities. However, this only affects user authentication, while authorization decisions can be adjusted by local site administrators by adapting the gPlazma configuration.

To allow local site’s administrators to override remote security settings, write access can be further restricted to few directories (based on the local namespace, the pnfs). Setting xrootd access to read-only has the highest priority, overriding all other settings.
Other configuration options

The xrootd-door has several other configuration properties. You can configure various timeout parameters, the thread pool sizes on pools, queue buffer sizes on pools, the xrootd root path, the xrootd user and the xrootd IO queue. Full descriptions on the effect of those can be found in /usr/share/dcache/defaults/xrootd.properties.
Chapter 14. dCache Storage Resource Manager

Introduction

Storage Resource Managers (SRMs) are middleware components whose function is to provide dynamic space allocation and file management on shared storage components on the Grid. SRMs support protocol negotiation and a reliable replication mechanism. The SRM specification [https://sdm.lbl.gov/srm-wg/doc/SRM.v2.2.html] standardizes the interface, thus allowing for a uniform access to heterogeneous storage elements.

The SRM utilizes the Grid Security Infrastructure (GSI) for authentication. The SRM is a Web Service implementing a published WSDL document. Please visit the SRM Working Group Page [http://sdm.lbl.gov/srm-wg/] to see the SRM Version 1.1 and SRM Version 2.2 protocol specification documents.

The SRM protocol uses HTTP over GSI as a transport. The dCache SRM implementation added HTTPS as a transport layer option. The main benefits of using HTTPS rather than HTTP over GSI is that HTTPS is a standard protocol and has support for sessions, improving latency in case a client needs to connect to the same server multiple times. The current implementation does not offer a delegation service. Hence srmCopy will not work with SRM over HTTPS. A separate delegation service will be added in a later release.

Configuring the srmp service

The Basic Setup

Like other services, the srmp service can be enabled in the layout file /etc/dcache/layouts/my-layout of your dCache installation. For an overview of the layout file format, please see the section called “Defining domains and services”.

To enable SRM in a separate srmp-${host.name}Domain in dCache, add the following lines to your layout file:

```
[srmp-${host.name}Domain]
[srmp-${host.name}Domain/srmp]
```

The use of the srmp service requires an authentication setup, see Chapter 12, Authorization in dCache for a general description or the section called “Authentication and Authorization in dCache” for an example setup with X.509 certificates.

You can now copy a file into your dCache using the SRM,

**Note**

Please make sure to use latest srmcp client otherwise you will need to specify -2 in order to use the right version.

```
[user] $ srmcp file:///bin/sh srm://dcache.example.org:8443/data/world-writeable/srm-test-file
```

copy it back
[user] $ srmcp srm://dcache.example.org:8443/data/world-writable/srm-test-file file:///tmp/srmtestfile.tmp

and delete it

[.user] $ srmrm srm://dcache.example.org:8443/data/world-writable/srm-test-file

**Important srm configuration options**

The defaults for the following configuration parameters can be found in the .properties files in the directory /usr/share/dcache/defaults.

If you want to modify parameters, copy them to /etc/dcache/dcache.conf or to your layout file /etc/dcache/layouts/mylayout and update their value.

Change the value for srmDatabaseHost=localhost in the layout file.

In the file /usr/share/dcache/defaults/srm.properties you will find the default values

```
# ---- Database name
srmDbName=dcache

# ---- Database user name
srmDbUser=srmdcache
```

The defaults for the configuration parameters for the SRM service can be found in /usr/share/dcache/defaults/dcache.properties.

```
srmCopyReqThreadPoolSize=250
remoteGsiftpMaxTransfers=${srmCopyReqThreadPoolSize}
```

If you want to modify these values make sure that both srmCopyReqThreadPoolSize and remoteGsiftpMaxTransfers are set to the same values. The common value should be the roughly equal to the maximum number of the SRM - to - SRM copies your system can sustain.

So if you think about 3 gridftp transfers per pool and you have 30 pools then the number should be 3x30=90.

```
srmCopyReqThreadPoolSize=90
remoteGsiftpMaxTransfers=90
```

US-CMS T1 has:

```
srmCopyReqThreadPoolSize=2000
remoteGsiftpMaxTransfers=2000
```

**Note**

SRM might produce a lot of log entries, especially if it runs in debug mode. It is recommended to make sure that logs are redirected into a file on a large disk.
Utilization of Space Reservations for Data Storage

SRM version 2.2 introduced a concept of space reservation. Space reservation guarantees that the requested amount of storage space of a specified type is made available by the storage system for a specified amount of time.

The dCache administrator can make space reservations for VOs (see the section called “SpaceManager configuration for Explicit Space Reservations”). Each space reservation has an associated ID (or space token). VOs then can copy directly into space tokens assigned to them by the dcache administrator.

When a file is about to be transferred to a storage system, the space available in the space reservation is checked if it can accommodate the entire file. If yes, this chunk of space is marked as allocated, so that it can not be taken by another, concurrently transferred file. If the file is transferred successfully the allocated space becomes used space within the space reservation, else the allocated space is released back to the space reservation.

SRM space reservation can be assigned a non-unique description which can be used to query the system for space reservations with a given description.

dCache only manages write space, i.e. space on disk can be reserved only for write operations. Once files are migrated to tape, and if no copy is required on disk, space used by these files is returned back into space reservation. When files are read back from tape and cached on disk, they are not counted as part of any space.

Properties of Space Reservation

The administrator can specify a RetentionPolicy and an AccessLatency for the space reservation.

RetentionPolicy describes the quality of the storage service that will be provided for the data (files) stored in this space reservation and AccessLatency describes the availability of this data. The specification requires that if a space reservation is given, then the specified RetentionPolicy or AccessLatency must match those of the space reservation.

The default values for the RetentionPolicy and AccessLatency can be changed in the file /etc/dcache/dcache.conf.

RetentionPolicy The values of RetentionPolicy used in dCache are REPLICA and CUSTODIAL.

- REPLICA corresponds to the lowest quality of the service, usually associated with storing a single copy of each file on the disk.

- CUSTODIAL is the highest quality service, usually interpreted as storage of the data on tape.

Once a file is written into a given space reservation, it inherits the reservation’s RetentionPolicy.

If the space reservation request does not specify a retention policy we will assign DefaultRetentionPolicy a retention policy by default. The default value is CUSTODIAL.
Edit the file `/etc/dcache/dcache.conf` to change the default value.

Change the default value to REPLICA.

```
DefaultRetentionPolicy=REPLICA
```

**AccessLatency**

The two values allowed for AccessLatency are NEARLINE and ONLINE.

- NEARLINE means that data stored in this reservation is allowed to migrate to permanent media. Retrieving these data may result in delays associated with preparatory steps that the storage system has to perform to make these data available for the user I/O (e.g., staging data from tape to a disk cache).

- ONLINE means that data is readily available allowing for faster access.

In case of dCache ONLINE means that there will always be a copy of the file on disk, while NEARLINE does not provide such guarantee. As with RetentionPolicy, once a file is written into a given space reservation, it inherits the reservation’s AccessLatency.

If a space reservation request does not specify an access latency we will assign `DefaultAccessLatencyForSpaceReservation` an access latency by default. The default value is NEARLINE.

Edit the file `/etc/dcache/dcache.conf` to change the default value.

Change the default value to ONLINE.

```
DefaultAccessLatencyForSpaceReservation=ONLINE
```

**Important**

Please make sure to use capital letters for REPLICA, CUSTODIAL, ONLINE and NEARLINE otherwise you will receive an error message.

**dCache specific concepts**

**Activating SRM SpaceManager**

In order to enable the SRM SpaceManager you need to add the spacemanager service to your layout file

```
[srm-${host.name}Domain]
[srm-${host.name}Domain/srm]
[srm-${host.name}Domain/spacemanager]
```

and add (uncomment) the following definition in the file `/etc/dcache/dcache.conf`

```
srmSpaceManagerEnabled=yes
```
Explicit and Implicit Space Reservations for Data Storage in dCache

Explicit Space Reservations

Each SRM space reservation is made against the total available disk space of a particular link group. If dCache is configured correctly each byte of disk space, that can be reserved, belongs to one and only one link group. See the section called “SpaceManager configuration for Explicit Space Reservations” for a detailed description.

**Important**

Make sure that no pool belongs to more than one pool group, no pool group belongs to more than one link and no link belongs to more than one link group.

If a space reservation is specified, the file will be stored in it (assuming the user has permission to do so in the name space).

Files written into a space made within a particular link group will end up on one of the pools belonging to this link group. The difference between the link group’s available space and the sum of all the current space reservation sizes is the available space in the link group.

The total space in dCache that can be reserved is the sum of the available spaces of all link groups.

Implicit Space Reservations

dCache can perform implicit space reservations for non-SRM transfers, SRM Version 1 transfers and for SRM Version 2.2 data transfers that are not given the space token explicitly. The parameter that enables this behavior is `srmImplicitSpaceManagerEnabled`, which is described in the section called “SRM configuration for experts”. If no implicit space reservation can be made, the transfer will fail.

In case of SRM version 1.1 data transfers, when the access latency and retention policy cannot be specified, and in case of SRM V2.2 clients, when the access latency and retention policy are not specified, the default values will be used. First SRM will attempt to use the values of `AccessLatency` and `RetentionPolicy` tags from the directory to which a file is being written. If the tags are present, then the `AccessLatency` and `RetentionPolicy` will be set on basis of the system wide defaults, which are controlled by `DefaultRetentionPolicy` and `DefaultAccessLatencyForSpaceReservation` variables in `/etc/dcache/dcache.conf`.

You can check if the `AccessLatency` and `RetentionPolicy` tags are present by using the following commands:

```
[root] # /usr/bin/chimera-cli lstag /path/to/directory
Total: numberOfTags
tag1
tag2
..
AccessLatency
RetentionPolicy
```

If the output contains the lines `AccessLatency` and `RetentionPolicy` then the tags are already present and you can get the actual values of these tags by executing the following commands, which are shown together with example outputs:
dCache Storage Resource Manager

The valid AccessLatency values are ONLINE and NEARLINE, valid RetentionPolicy values are REPLICA and CUSTODIAL.

To create/change the values of the tags, please execute:

```bash
[root] # /usr/bin/chimera-cli readtag /data/experiment-a AccessLatency
ONLINE
[root] # /usr/bin/chimera-cli readtag /data/experiment-a RetentionPolicy
CUSTODIAL
```

Note

Some clients also have default values, which are used when not explicitly specified by the user. In this case server side defaults will have no effect.

Note

If the implicit space reservation is not enabled the pools in the link groups will be excluded from consideration and only the remaining pools will be considered for storing the incoming data, and classical pool selection mechanism will be used.

**SpaceManager configuration for Explicit Space Reservations**

**SRM SpaceManager and Link Groups**

SpaceManager is making reservations against free space available in link groups. The total free space in the given link group is the sum of available spaces in all links. The available space in each link is the sum of all sizes of available space in all pools assigned to a given link. Therefore for the space reservation to work correctly it is essential that each pool belongs to one and only one link, and each link belongs to only one link group. Link groups are assigned several parameters that determine what kind of space the link group corresponds to and who can make reservations against this space.

**Making a Space Reservation**

Now that the SRM SpaceManager is activated you can make a space reservation. As mentioned above you need link groups to make a space reservation.

**Prerequisites for Space Reservations**

Login to the admin interface and cd to the cell SrmSpaceManager.

```
[user] $ ssh -c blowfish -p 22223 -l admin headnode.example.org
(local) admin > cd SrmSpaceManager
```

Type ls to get information about reservations and link groups.

```
(SrmSpaceManager) admin > ls
```
This output tells you that there are no reservations yet and no link groups. As there are no link groups no space can be reserved.

**The Link Groups**

For a general introduction about link groups see the section called “Link Groups”.

In this example we will create a link group for the VO desy. In order to do so we need to have a pool, a pool group and a link. Moreover, we define unit groups named any-store, world-net and any-protocol. (See the section called “Types of Units”.)

Define a pool in your layout file, add it to your pool directory and restart the poolDomain.

```plaintext
[poolDomain]
[poolDomain/pool]
path=/srv/dcache/spacemanager-pool
name=spacemanager-pool

[root] # mkdir -p /srv/dcache/spacemanager-pool
[root] # /usr/bin/dcache restart
```

In the Admin Interface cd to the PoolManager and create a pool group, a link and a link group.

```plaintext
($rmSpaceManager) admin > ..
(local) admin > cd PoolManager
(PoolManager) admin > psu create pgroup spacemanager_poolGroup
(PoolManager) admin > psu addto pgroup spacemanager_poolGroup spacemanager-pool
(PoolManager) admin > psu removefrom pgroup default spacemanager-pool
(PoolManager) admin > psu create link spacemanager_WriteLink any-store world-net any-protocol
(PoolManager) admin > psu set link spacemanager_WriteLink -readpref=10 -writepref=10 -cachepref=0 -p2ppref=-1
(PoolManager) admin > psu add link spacemanager_WriteLink spacemanager_poolGroup
(PoolManager) admin > psu create linkGroup spacemanager_WriteLinkGroup
(PoolManager) admin > psu set linkGroup custodialAllowed spacemanager_WriteLinkGroup true
(PoolManager) admin > psu set linkGroup replicaAllowed spacemanager_WriteLinkGroup true
(PoolManager) admin > psu set linkGroup nearlineAllowed spacemanager_WriteLinkGroup true
(PoolManager) admin > psu set linkGroup onlineAllowed spacemanager_WriteLinkGroup true
(PoolManager) admin > save
(PoolManager) admin > ..
```

Check whether the link group is available.

```plaintext
(local) admin > cd $rmSpaceManager
($rmSpaceManager) admin > ls
Reservations:
total number of reservations: 0
total number of bytes reserved: 0

LinkGroups:
0 Name:spacemanager_WriteLinkGroup FreeSpace:7278624768 ReservedSpace:0 AvailableSpace:7278624768
VOs: onlineAllowed:true nearlineAllowed:false replicaAllowed:true custodialAllowed:true
UpdateTime:Mon Nov 28 12:12:51 CET 2011(132247871030)
```
The link group spacemanager_WriteLinkGroup was created and has the id 0.

**The SpaceManagerLinkGroupAuthorizationFile**

Now you need to edit the LinkGroupAuthorization.conf file. This file contains a list of the link groups and all the VOs and the VO Roles that are permitted to make reservations in a given link group.

Specify the location of the LinkGroupAuthorization.conf file in the /etc/dcache/ dcache.conf file.

SpaceManagerLinkGroupAuthorizationFileName=/path/to/LinkGroupAuthorization.conf

The file LinkGroupAuthorization.conf has following syntax:

LinkGroup NameOfLinkGroup followed by the list of the Fully Qualified Attribute Names (FQANs). Each FQAN on a separate line, followed by an empty line, which is used as a record separator, or by the end of the file.

FQAN is usually a string of the form VO/Role=VORole. Both VO and VORole could be set to *, in this case all VOs or VO Roles will be allowed to make reservations in this link group. Any line that starts with # is a comment and may appear anywhere.

Note

You do not need to restart the srm or dCache after changing the LinkGroupAuthorization.conf file. The changes will be applied automatically after a few minutes.

Use **update link groups** to be sure that the LinkGroupAuthorization.conf file and the link groups have been updated.

(SrmSpaceManager) admin > update link groups
update started

In the example above you created the link group spacemanager_WriteLinkGroup. Now you want to allow members of the VO desy with the role production to make a space reservation in this link group.

In this more general example for a SpaceManagerLinkGroupAuthorizationFile members of the VO desy with role test get the right to make a space reservation in a link group called desy-
test-LinkGroup. Moreover, all members of the VO desy get the right to make a reservation in the link group called desy-anyone-LinkGroup and anyone will get the right to make a space reservation in the link group called default-LinkGroup.

```plaintext
#SpaceManagerLinkGroupAuthorizationFile
# this is comment and is ignored
LinkGroup desy-test-LinkGroup
/desy/Role=/test
LinkGroup desy-anyone-LinkGroup
/desy/Role=* 
LinkGroup default-LinkGroup
# allow anyone :-
*/Role=* 
```

Making and Releasing a Space Reservation as dCache Administrator

Making a Space Reservation

Now you can make a space reservation for the VO desy.

```plaintext
(SrmSpaceManager) admin > reserve -vog=/desy -vor=production -desc=DESY_TEST 5000000 10000
110000 voGroup:/desy voRole:production retentionPolicy:CUSTODIAL accessLatency:NEARLINE
linkGroupId:0 size:5000000 created:Fri Dec 09 12:43:48 CET 2011 lifetime:1000000ms
expiration:Fri Dec 09 15:30:28 CET 2011 description:DESY_TEST state:RESERVED used:0 allocated:0
The id of the space token is 110000.
```

Check the status of the reservation by

```plaintext
(SrmSpaceManager) admin > ls
Reservations:
110000 voGroup:/desy voRole:production retentionPolicy:CUSTODIAL accessLatency:NEARLINE
linkGroupId:0 size:5000000 created:Fri Dec 09 12:43:48 CET 2011 lifetime:1000000ms
expiration:Fri Dec 09 15:30:28 CET 2011 description:DESY_TEST state:RESERVED used:0 allocated:0
total number of reservations: 1
total number of bytes reserved: 5000000
LinkGroups:
0 Name:spacemanager_WriteLinkGroup FreeSpace:23747563520 ReservedSpace:5000000
total number of linkGroups: 1
total number of bytes reservable: 23742563520
total number of bytes reserved : 5000000
last time all link groups were updated: Fri Dec 09 12:49:29 CET 2011(1323431369046)
```

You can now copy a file into that space token.

```plaintext
[user] $ srmcp file:///bin/sh srm://dcache.example.org:8443/data/world-writable/space-token-test-file -space_token=110000
```

Now you can check via the Webadmin Interface or the Web Interface that the file has been copied to the pool spacemanager-pool.

There are several parameters to be specified for a space reservation.

```plaintext
(SrmSpaceManager) admin > reserve [-vog=voGroup] [-vor=voRole] [-acclat=AccessLatency] \
```

128
dCache Storage Resource Manager

[-retpol=RetentionPolicy] [-desc=Description] [-lgid=LinkGroupId] [-lg=LinkGroupName] 
sizeInBytes lifetimeInSecs

[-vog=voGroup] voGroup should match the VO you specified in the LinkGroupAuthorization.conf file. If you do not want to make a space reservation for a certain VO then the entry in the LinkGroupAuthorization.conf should read

```
LinkGroup NameOfLinkGroup
*/Role=*```

[-vor=voRole] voRole can be specified if it is used in the LinkGroupAuthorization.conf file.

[-acclat=AccessLatency] AccessLatency needs to match one of the access latencies allowed for the link group.

[-retpol=RetentionPolicy] RetentionPolicy needs to match one of the retention policies allowed for the link group.

[-desc=Description] You can chose a value to describe your space reservation.

[-lgid=LinkGroupId] You can either use the LinkGroupId to make a space reservation or

[-lg=LinkGroupName] you use the LinkGroupName to make a space reservation.

sizeInBytes The size of the space reservation should be specified in bytes.

timeInSecs The life time of the space reservation should be specified in seconds. Choose "-1" for a space reservation that will never expire (use quotes around the negative one).

Releasing a Space Reservation
If a space reservation is not needet anymore it can be released with

```
(SrmSpaceManager) admin > release spaceTokenId
```

You can see that the value for state has changed from RESERVED to RELEASED

Making and Releasing a Space Reservation as a User

A user who has been given the right to make a space reservation can make a space reservation. To achieve this the right entry in the LinkGroupAuthorization.conf file is required.
VO based Authorization Prerequisites

In order to be able to take advantage of the virtual organization (VO) infrastructure and VO based authorization and VO based access control to the space in dCache, certain things need to be in place:

• User needs to be registered with the VO.

• User needs to use `voms-proxy-init` to create a VO proxy.

• dCache needs to use gPlazma with modules that extract VO attributes from the user’s proxy. (See Chapter 12, Authorization in dCache, have a look at `gplazmalite-vorole-mapping` plugin and see the section called “Authentication and Authorization in dCache” for an example with `gplazmalite-vorole-mapping`.

Only if these 3 conditions are satisfied the VO based authorization of the SpaceManager will work.

VO based Access Control Configuration

As mentioned above dCache space reservation functionality access control is currently performed at the level of the link groups. Access to making reservations in each link group is controlled by the `SpaceManagerLinkGroupAuthorizationFile`.

This file contains a list of the link groups and all the VOs and the VO Roles that are permitted to make reservations in a given link group.

When a SRM Space Reservation request is executed, its parameters, such as reservation size, lifetime, AccessLatency and RetentionPolicy as well as user’s VO membership information is forwarded to the SRM SpaceManager.

Once a space reservation is created, no access control is performed, any user can store the files in this space reservation, provided he or she knows the exact space token.

Making and Releasing a Space Reservation

A user who is given the rights in the `SpaceManagerLinkGroupAuthorizationFile` can make a space reservation by

```bash
[user] $ srm-reserve-space -retention_policy=RetentionPolicy -lifetime=lifetimeInSecs -desired_size=sizeInBytes -guaranteed_size=sizeInBytes srm://example.org:8443
Space token =SpaceTokenId
```

and release it by

```bash
[user] $ srm-release-space srm://example.org:8443 -space_token=SpaceTokenId
```

**Note**

Please note that it is obligatory to specify the retention policy while it is optional to specify the access latency.

```bash
[user] $ srm-reserve-space -retention_policy=REPLICA -lifetime=300 -desired_size=5500000 -guaranteed_size=5500000 srm://srm.example.org:8443
Space token =110044
```

The space reservation can be released by:
Space Reservation without VOMS certificate

If a client uses a regular grid proxy, created with `grid-proxy-init`, and not a VO proxy, which is created with the `voms-proxy-init`, when it is communicating with SRM server in dCache, then the VO attributes can not be extracted from its credential. In this case the name of the user is extracted from the Distinguished Name (DN) to use name mapping. For the purposes of the space reservation the name of the user as mapped by `gplazma` is used as its VO Group name, and the VO Role is left empty. The entry in the `SpaceManagerLinkGroupAuthorizationFile` should be:

```
#LinkGroupAuthorizationFile
#
userName
```

Space Reservation for non SRM Transfers

Edit the file `/etc/dcache/dcache.conf` to enable space reservation for non SRM transfers.

```
SpaceManagerReserveSpaceForNonSRMTransfers=true
```

If the `spacemanager` is enabled, `SpaceManagerReserveSpaceForNonSRMTransfers` is set to `true`, and if the transfer request comes from a door, and there was no prior space reservation made for this file, the `SpaceManager` will try to reserve space before satisfying the request.

Possible values are `true` or `false` and the default value is `false`.

**SRM configuration for experts**

There are a few parameters in `/usr/share/dcache/defaults/*.properties` that you might find useful for nontrivial SRM deployment.

```

```

SRMSpaceManagerEnabled

`SRMSpaceManagerEnabled` tells if the space management is activated in SRM.

Possible values are `yes` and `no`. Default is `yes`.

Usage example:

```
SRMSpaceManagerEnabled=yes
```

```

```

SRMImplicitSpaceManagerEnabled

`SRMImplicitSpaceManagerEnabled` tells if the space should be reserved for SRM Version 1 transfers and for SRM Version 2 transfers that have no space token specified. Will have effect only if `SRMSpaceManagerEnabled`.

Possible values are `yes` and `no`. This is enabled by default. It has no effect if `SRMSpaceManagerEnabled` is set to `no`.

Usage example:
**overwriteEnabled**

overwriteEnabled tells SRM and GridFTP servers if the overwrite is allowed. If enabled on the SRM node, should be enabled on all GridFTP nodes.

Possible values are `yes` and `no`. Default is `no`.

Usage example:

```plaintext
overwriteEnabled=yes
```

**srmOverwriteByDefault**

srmOverwriteByDefault Set this to `true` if you want overwrite to be enabled for SRM v1.1 interface as well as for SRM v2.2 interface when client does not specify desired overwrite mode. This option will be considered only if overwriteEnabled is set to `yes`.

Possible values are `true` and `false`. Default is `false`.

Usage example:

```plaintext
srmOverwriteByDefault=false
```

**srmDatabaseHost**

srmDatabaseHost tells SRM which database host to connect to.

Default value is `localhost`.

Usage example:

```plaintext
srmDatabaseHost=database-host.example.org
```

**spaceManagerDatabaseHost**

spaceManagerDatabaseHost tells SpaceManager which database host to connect to.

Default value is `localhost`.

Usage example:

```plaintext
spaceManagerDatabaseHost=database-host.example.org
```

**pinManagerDbHost**

pinManagerDbHost tells PinManager which database host to connect to.

Default value is `localhost`.

Usage example:
pinManagerDbHost=database-host.example.org

srmDbName

`srmDbName` tells SRM which database to connect to.

Default value is `dcache`.

Usage example:
```
srmDbName=dcache
```

srmDbUser

`srmDbUser` tells SRM which database user name to use when connecting to database. Do not change unless you know what you are doing.

Default value is `srmdcache`.

Usage example:
```
srmDbUser=srmdcache
```

srmDbPassword

`srmDbPassword` tells SRM which database password to use when connecting to database. The default value is `srmdcache`.

Usage example:
```
srmDbPassword=NotVerySecret
```

srmPasswordFile

`srmPasswordFile` tells SRM which database password file to use when connecting to database. Do not change unless you know what you are doing. It is recommended that MD5 authentication method is used. To learn about file format please see http://www.postgresql.org/docs/8.1/static/libpq-pgpass.html. To learn more about authentication methods please visit http://www.postgresql.org/docs/8.1/static/encryption-options.html. Please read "Encrypting Passwords Across A Network" section.

This option is not set by default.

Usage example:
```
srmPasswordFile=/root/.pgpass
```

srmRequestHistoryDatabaseEnabled

`srmRequestHistoryDatabaseEnabled` enables logging of the transition history of the SRM request in the database. The request transitions can be examined through the command line interface.
Activation of this option might lead to the increase of the database activity, so if the PostgreSQL load generated by SRM is excessive, disable it.

Possible values are true and false. Default is false.

Usage example:

```
srmRequestHistoryDatabaseEnabled=true
```

**srmDbLogEnabled**

`srmDbLogEnabled` tells SRM to store the information about the remote (copy, srmCopy) transfer details in the database. Activation of this option might lead to the increase of the database activity, so if the PostgreSQL load generated by SRM is excessive, disable it.

Possible values are true and false. Default is false.

Usage example:

```
srmDbLogEnabled=false
```

**srmVersion**

`srmVersion` is not used by SRM; it was mentioned that this value is used by some publishing scripts.

Default is version1.

**pnfsSrmPath**

`pnfsSrmPath` tells SRM what the root of all SRM paths is in pnfs. SRM will prepend path to all the local SURL paths passed to it by SRM client. So if the `pnfsSrmPath` is set to `/pnfs/fnal.gov/THISISTHEPNFSSRMPATH` and someone requests the read of `srm:// srm.example.org:8443/file1`, SRM will translate the SURL path `/file1` into `/pnfs/fnal.gov/THISISTHEPNFSSRMPATH/file1`. Setting this variable to something different from `/` is equivalent of performing Unix `chroot` for all SRM operations.

Default value is `/`.

Usage example:

```
pnfsSrmPath="/pnfs/fnal.gov/data/experiment"
```

**parallelStreams**

`parallelStreams` specifies the number of the parallel streams that SRM will use when performing third party transfers between this system and remote GSI-FTP servers, in response to SRM v1.1 copy or SRM V2.2 srmCopy function. This will have no effect on srmPrepareToPut and srmPrepareToGet command results and parameters of GridFTP transfers driven by the SRM clients.

Default value is 10.

Usage example:
**srmBufferSize**

`srmBufferSize` specifies the number of bytes to use for the in memory buffers for performing third party transfers between this system and remote GSI-FTP servers, in response to SRM v1.1 copy or SRM V2.2 srmCopy function. This will have no effect on srmPrepareToPut and srmPrepareToGet command results and parameters of GridFTP transfers driven by the SRM clients.

Default value is 1048576.

Usage example:

```
srmBufferSize=1048576
```

**srmTcpBufferSize**

`srmTcpBufferSize` specifies the number of bytes to use for the tcp buffers for performing third party transfers between this system and remote GSI-FTP servers, in response to SRM v1.1 copy or SRM V2.2 srmCopy function. This will have no effect on srmPrepareToPut and srmPrepareToGet command results and parameters of GridFTP transfers driven by the SRM clients.

Default value is 1048576.

Usage example:

```
srmTcpBufferSize=1048576
```

**srmAuthzCacheLifetime**

`srmAuthzCacheLifetime` specifies the duration that authorizations will be cached. Caching decreases the volume of messages to the gPlazma cell or other authorization mechanism. To turn off caching, set the value to 0.

Default value is 120.

Usage example:

```
srmAuthzCacheLifetime=60
```

**srmGetLifeTime, srmPutLifeTime and srmCopyLifeTime**

`srmGetLifeTime`, `srmPutLifeTime` and `srmCopyLifeTime` specify the lifetimes of the srmPrepareToGet (srmBringOnline) srmPrepareToPut and srmCopy requests lifetimes in millisecond. If the system is unable to fulfill the requests before the request lifetimes expire, the requests are automatically garbage collected.

Default value is 14400000 (4 hours)

Usage example:

```
srmGetLifeTime=14400000
```
srnGetReqMaxReadyRequests, srnPutReqMaxReadyRequests, srnGetReqReadyQueueSize and srnPutReqReadyQueueSize

srnGetReqMaxReadyRequests and srnPutReqMaxReadyRequests specify the maximum number of the files for which the transfer URLs will be computed and given to the users in response to SRM get (srnPrepareToGet) and put (srnPrepareToPut) requests. The rest of the files that are ready to be transferred are put on the Ready queues, the maximum length of these queues are controlled by srnGetReqReadyQueueSize and srnPutReqReadyQueueSize parameters. These parameters should be set according to the capacity of the system, and are usually greater than the maximum number of the GridFTP transfers that this dCache instance GridFTP doors can sustain.

Usage example:

```
srnGetReqReadyQueueSize=10000
srnPutReqMaxReadyRequests=2000
srnGetReqReadyQueueSize=10000
srnPutReqMaxReadyRequests=1000
```

srnCopyReqThreadPoolSize and remoteGsiftpMaxTransfers

srnCopyReqThreadPoolSize and remoteGsiftpMaxTransfers. srnCopyReqThreadPoolSize is used to specify how many parallel srnCopy file copies to execute simultaneously. Once the SRM contacted the remote SRM system, and obtained a Transfer URL (usually GSI-FTP URL), it contacts a Copy Manager module (usually RemoteGSIFTPTransferManager), and asks it to perform a GridFTP transfer between the remote GridFTP server and a dCache pool. The maximum number of simultaneous transfers that RemoteGSIFTPTransferManager will support is remoteGsiftpMaxTransfers, therefore it is important that remoteGsiftpMaxTransfers is greater than or equal to srnCopyReqThreadPoolSize.

Usage example:

```
srnCopyReqThreadPoolSize=250
remoteGsiftpMaxTransfers=260
```

srnCustomGetHostByAddr

srnCustomGetHostByAddr srnCustomGetHostByAddr enables using the BNL developed procedure for host by IP resolution if standard InetAddress method failed.

Usage example:

```
srnCustomGetHostByAddr=true
```

RecursiveDirectoryCreation

RecursiveDirectoryCreation allows or disallows automatic creation of directories via SRM, allow=true, disallow=false.
Automatic directory creation is allowed by default.

Usage example:

```
RecursiveDirectoryCreation=true
```

### hostCertificateRefreshPeriod

This option allows you to control how often the SRM door will reload the server’s host certificate from the filesystem. For the specified period, the host certificate will be kept in memory. This speeds up the rate at which the door can handle requests, but also causes it to be unaware of changes to the host certificate (for instance in the case of renewal).

By changing this parameter you can control how long the host certificate is cached by the door and consequently how fast the door will be able to detect and reload a renewed host certificate.

Please note that the value of this parameter has to be specified in seconds.

Usage example:

```
hostCertificateRefreshPeriod=86400
```

### trustAnchorRefreshPeriod

The `trustAnchorRefreshPeriod` option is similar to `hostCertificateRefreshPeriod`. It applies to the set of CA certificates trusted by the SRM door for signing end-entity certificates (along with some metadata, these form so called trust anchors). The trust anchors are needed to make a decision about the trustworthiness of a certificate in X.509 client authentication. The GSI security protocol used by SRM builds upon X.509 client authentication.

By changing this parameter you can control how long the set of trust anchors remains cached by the door. Conversely, it also influences how often the door reloads the set of trusted certificates.

Please note that the value of this parameter has to be specified in seconds.

**Tip**

Trust-anchors usually change more often than the host certificate. Thus, it might be sensible to set the refresh period of the trust anchors lower than the refresh period of the host certificate.

Usage example:

```
trustAnchorRefreshPeriod=3600
```

### Configuring the PostgreSQL Database

We highly recommend to make sure that PostgreSQL database files are stored on a separate disk that is not used for anything else (not even PostgreSQL logging). BNL Atlas Tier 1 observed a great improvement in srm-database communication performance after they deployed PostgreSQL on a separate dedicated machine.
SRM or srm monitoring on a separate node

If SRM or srm monitoring is going to be installed on a separate node, you need to add an entry in the file /var/lib/pgsql/data/pg_hba.conf for this node as well:

```
host    all         all     monitoring node     trust
host    all         all     srm node         trust
```

The file postgresql.conf should contain the following:

```
#to enable network connection on the default port
max_connections = 100
port = 5432
...
shared_buffers = 114688
...
work_mem = 10240
...
#to enable autovacuuming
stats_row_level = on
autovacuum = on
autovacuum_vacuum_threshold = 500  # min # of tuple updates before vacuum
autovacuum_analyze_threshold = 250  # min # of tuple updates before analyze
autovacuum_vacuum_scale_factor = 0.2  # fraction of rel size before vacuum
autovacuum_analyze_scale_factor = 0.1  # fraction of rel size before analyze

# setting vacuum_cost_delay might be useful to avoid autovacuum penalize general performance
# it is not set in US-CMS T1 at Fermilab
#
# In IN2P3 add_missing_from = on
# In Fermilab it is commented out

# - Free Space Map -
max_fsm_pages = 500000

# - Planner Cost Constants -
effective_cache_size = 16384  # typically 8KB each
```

General SRM Concepts (for developers)

The SRM service

dCache SRM is implemented as a Web Service running in a Jetty servlet container and an Axis Web Services engine. The Jetty server is executed as a cell, embedded in dCache and started automatically by the SRM service. Other cells started automatically by SRM are SpaceManager, PinManager and RemoteGSIFTPTransferManager. Of these services only SRM and SpaceManager require special configuration.

The SRM consists of the five categories of functions:

- Space Management Functions
- Data Transfer Functions
- Request Status Functions
- Directory Functions
Space Management Functions

SRM version 2.2 introduces a concept of space reservation. Space reservation guarantees that the requested amount of storage space of a specified type is made available by the storage system for a specified amount of time.

We use three functions for space management:

- `srmReserveSpace`
- `SrmGetSpaceMetadata`
- `srmReleaseSpace`

Space reservation is made using the `srmReserveSpace` function. In case of successful reservation, a unique name, called space token is assigned to the reservation. A space token can be used during the transfer operations to tell the system to put the files being manipulated or transferred into an associated space reservation. A storage system ensures that the reserved amount of the disk space is indeed available, thus providing a guarantee that a client does not run out of space until all space promised by the reservation has been used. When files are deleted, the space is returned to the space reservation.

dCache only manages write space, i.e. space on disk can be reserved only for write operations. Once files are migrated to tape, and if no copy is required on disk, space used by these files is returned back into space reservation. When files are read back from tape and cached on disk, they are not counted as part of any space. SRM space reservation can be assigned a non-unique description that can be used to query the system for space reservations with a given description.

Properties of the SRM space reservations can be discovered using the `SrmGetSpaceMetadata` function.

Space Reservations might be released with the function `srmReleaseSpace`.

For a complete description of the available space management functions please see the SRM Version 2.2 Specification [http://sdm.lbl.gov/srm-wg/doc/SRM.v2.2.html#_Toc241633085].

Data Transfer Functions

Surls and TURLs

SRM defines a protocol named SRM, and introduces a way to address the files stored in the SRM managed storage by site URL (SURL of the format `srm://<host>:<port>/[<web service path>?SFN=]<path>`.

Examples of the SURLs a.k.a. SRM URLs are:

```
srm://fapl110.fnal.gov:8443/srm/managerv2?SFN=/pnfs/fnal.gov/data/test/file1
srm://srm.cern.ch:8443/castor/cern.ch/cms/store/cmsfile23
```

A transfer URL (TURL) encodes the file transport protocol in the URL.

```
gsiftp://gridftpdoor.fnal.gov:2811/data/test/file1
```
SRM version 2.2 provides three functions for performing data transfers:

- `srmPrepareToGet`
- `srmPrepareToPut`
- `srmCopy`

(in SRM version 1.1 these functions were called `get`, `put` and `copy`).

All three functions accept lists of SURLs as parameters. All data transfer functions perform file/directory access verification and `srmPrepareToPut` and `srmCopy` check if the receiving storage element has sufficient space to store the files.

`srmPrepareToGet` prepares files for read. These files are specified as a list of source SURLs, which are stored in an SRM managed storage element. `srmPrepareToGet` is used to bring source files online and assigns transfer URLs (TURLs) that are used for actual data transfer.

`srmPrepareToPut` prepares an SRM managed storage element to receive data into the list of destination SURLs. It prepares a list of TURLs where the client can write data into.

Both functions support transfer protocol negotiation. A client supplies a list of transfer protocols and the SRM server computes the TURL using the first protocol from the list that it supports. Function invocation on the Storage Element depends on implementation and may range from simple SURL to TURL translation to stage from tape to disk cache and dynamic selection of transfer host and transfer protocol depending on the protocol availability and current load on each of the transfer server load.

The function `srmCopy` is used to copy files between SRM managed storage elements. If both source and target are local to the SRM, it performs a local copy. There are two modes of remote copies:

- **PULL mode** : The target SRM initiates an `srmCopy` request. Upon the client's `srmCopy` request, the target SRM makes a space at the target storage, executes `srmPrepareToGet` on the source SRM. When the TURL is ready at the source SRM, the target SRM transfers the file from the source TURL into the prepared target storage. After the file transfer completes, `srmReleaseFiles` is issued to the source SRM.

- **PUSH mode** : The source SRM initiates an `srmCopy` request. Upon the client's `srmCopy` request, the source SRM prepares a file to be transferred out to the target SRM, executes `srmPrepareToPut` on the target SRM. When the TURL is ready at the target SRM, the source SRM transfers the file from the prepared source into the prepared target TURL. After the file transfer completes, `srmPutDone` is issued to the target SRM.

When a specified target space token is provided, the files will be located in the space associated with the space token.

SRM Version 2.2 `srmPrepareToPut` and `srmCopy` PULL mode transfers allow the user to specify a space reservation token or a RetentionPolicy and AccessLatency. Any of these parameters are optional, and it is up to the implementation to decide what to do, if these properties are not specified. The specification requires that if a space reservation is given, then the specified AccessLatency or RetentionPolicy must match those of the space reservation.

The Data Transfer Functions are asynchronous, an initial SRM call starts a request execution on the server side and returns a request status that contains a unique request token. The status of request is polled periodically by SRM get request status functions. Once a request is completed and the client receives the TURLs the data transfers are initiated. When the transfers are completed the client notifies the SRM.
server by executing `srmReleaseFiles` in case of `srmPrepareToGet` or `srmPutDone` in case of `srmPrepareToPut`. In case of `srmCopy`, the system knows when the transfers are completed and resources can be released, so it requires no special function at the end.

Clients are free to cancel the requests at any time by execution of `srmAbortFiles` or `srmAbortRequest`.

**Request Status Functions**

The functions for checking the request status are:

- `srmStatusOfReserveSpaceRequest`
- `srmStatusOfUpdateSpaceRequest`
- `srmStatusOfChangeSpaceForFilesRequest`
- `srmStatusOfChangeSpaceForFilesRequest`
- `srmStatusOfBringOnlineRequest`
- `srmStatusOfPutRequest`
- `srmStatusOfCopyRequest`

**Directory Functions**

SRM Version 2.2, interface provides a complete set of directory management functions. These are

- `srmLs`, `srmRm`
- `srmMkDir`, `srmRmDir`
- `srmMv`

**Permission functions**

SRM Version 2.2 supports the following three file permission functions:

- `srmGetPermission`
- `srmCheckPermission` and
- `srmSetPermission`

dCache contains an implementation of these functions that allows setting and checking of Unix file permissions.
Chapter 15. The statistics Service

The statistics service collects information on the amount of data stored on all pools and the total data flow including streams from and to tertiary storage systems.

Once per hour an ASCII file is produced, containing a table with information on the amount of used disk space and the data transferred starting midnight up to this point in time. Data is sorted per pool and storage class.

In addition to the hourly statistics, files are produced reporting on the daily, monthly and yearly dCache activities. An HTML tree is produced and updated once per hour allowing to navigate through the collected statistics information.

The Basic Setup

Define the statistics service in the domain, where the httpd is running.

```
[httpdDomain]
[httpdDomain/httpd]
...
[httpdDomain/statistics]
```

The statistics service automatically creates a directory tree, structured according to years, months and days.

Once per hour, a total.raw file is produced underneath the active year, month and day directories, containing the sum over all pools and storage classes of the corresponding time interval. The day directory contains detailed statistics per hour and for the whole day.

```
/var/lib/dcache/statistics/YYYY/total.raw
/var/lib/dcache/statistics/YYYY/MM/total.raw
/var/lib/dcache/statistics/YYYY/MM/DD/total.raw
/var/lib/dcache/statistics/YYYY/MM/DD/YYYY-MM-DD-day.raw
/var/lib/dcache/statistics/YYYY/MM/DD/YYYY-MM-DD-HH.raw
```

In the same directory tree the HTML files are created for each day, month and year.

```
/var/lib/dcache/statistics/YYYY/index.html
```

By default the path for the statistics data is /var/lib/dcache/statistics. You can modify this path by setting the property dcache.paths.statistics to a different value.

The Statistics Web Page

Point a web browser to your dCache webpage at http://head-node.example.org:2288/. On the bottom you find the link to Statistics.

The statistics data needs to be collected for a day before it will appear on the web page.

**Note**

You will get an error if you try to read the statistics web page right after you enabled the statistics as the web page has not yet been created.
Create data and the web page by logging in to the admin interface and running the commands `create stat` and `create html`.

```
(local) admin > cd PoolStatistics@httpdDomain
(PoolStatistics@)httpdDomain admin > create stat
Thread started for internal run
(PoolStatistics@)httpdDomain admin > create html
java.lang.NullPointerException
```

Now you can see a statistics web page.

Statistics is calculated once per hour at $HH:55$. The daily stuff is calculated at 23:55. Without manual intervention, it takes two midnights before all HTML statistics pages are available. There is a way to get this done after just one midnight. After the first midnight following the first startup of the statistics module, log into the PoolStatistics cell and run the following commands in the given sequence. The specified date has to be the Year/Month/Day of today.

```
(PoolStatistics@)httpdDomain admin > create html YYYY MM DD
done
(PoolStatistics@)httpdDomain admin > create html YYYY MM
done
(PoolStatistics@)httpdDomain admin > create html YYYY
done
(PoolStatistics@)httpdDomain admin > create html
```

You will see an empty statistics page at http://head-node.example.org:2288/statistics/.

### Explanation of the File Format of the xxx.raw Files

The file formats of the `/var/lib/dcache/statistics/YYYY/MM/DD/YYYY-MM-DD-HH.raw` and the `/var/lib/dcache/statistics/YYYY/MM/DD/YYYY-MM-DD-day.raw` files are similar. The file `/var/lib/dcache/statistics/YYYY/MM/DD/YYYY-MM-DD-HH.raw` does not contain columns 2 and 3 as these are related to the day and not to the hour.

The file format of the `/var/lib/dcache/statistics/YYYY/MM/DD/YYYY-MM-DD-day.raw` files:

```
# timestamp=1361364900897
# date=Wed Feb 20 13:55:00 CET 2013
# pool1 StoreA:GroupB@osm 21307929 10155 2466935 10155 0 925 0 0 0 85362 0
```

Format of YYYY-MM-DD-day.raw files.

<table>
<thead>
<tr>
<th>Column Number</th>
<th>Column Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Pool Name</td>
</tr>
<tr>
<td>1</td>
<td>Storage Class</td>
</tr>
<tr>
<td>Column Number</td>
<td>Column Description</td>
</tr>
<tr>

</tr>
<tr>
<td>13</td>
<td>Total Number of bytes transferred from dCache to HSM — orange bar</td>
</tr>
</tbody>
</table>

The YYYY/MM/DD/YYYY-MM-DD-HH.raw files do not contain line 2 and 3.
Chapter 16. dCache Webadmin-Interface

This part describes how to configure the Webadmin-interface which is a replacement for the old httpd-service and offers additional features to admins like sending admin-commands equal to those of admin to chosen cells.

The Webadmin-interface receives the information from dCache info service as XML which are parsed and presented. For authentication and authorisation it offers usage of username/password (currently KAuth-File) or grid-certificates talking to gPlazma. It also offers a non-authenticated, read-only mode.

If you are logged in as admin it is possible to send a command to multiple pools or a whole poolgroup in one go. It is even possible to send a command to any dCache-Cell.

From the technical point of view the Webadmin-interface uses a Jetty-Server which is embedded in an ordinary dCache-cell. It is using apache-wicket (a webfrontend-framework) and YAML (a CSS-Template Framework). The application is wired up by a Spring IOC-Container.

Installation

To enable your dCache to run the Webadmin-interface your system has to run the info service. For the authenticated mode a configured gPlazma is also required (see also the section called “gPlazma config example to work with authenticated webadmin”). The KAuth-File has to be on the same machine then the Webadmin for this to work. For a non-authenticated Webadmin you just need to add the Webadmin service to a domain and configure the port Webadmin will listen on - webadminHttpPort.

For authenticated mode the host certificate has to be imported into the dCache-keystore. In the grid world host certificates are usually signed by national Grid-CAs. Refer to the documentation provided by the Grid-CA to find out how to request a certificate. To import them into the dCache-keystore use this command:

```
[root] # dcache import hostcert
```

Now you have to initialise your truststore (this is the certificate-store used for the SSL connections) by using this command:

```
[root] # dcache import cacerts
```

Webadmin-interface uses the same truststore as WebDAV, so maybe you can skip this step.

You can enable the Webadmin interface by adding the service (Webadmin) to a domain.

```
[webadminDomain]
[webadminDomain/webadmin]
webadminDCacheInstanceName=coolName
webadminAuthenticated=true
webadminAdminGid=1000
```

The default value for the webadminHttpsPort is 8444 and for the webadminHttpPort it is 8080. Have a look at the following example to see how to modify these values.

```
[webadminDomain]
```
The most important value is `webadminAdminGid`, because it configures who is allowed to alter dCache behaviour, which certainly should not be everyone:

```properties
# ---- GID a user has to have to be considered an Admin of webadmininterface
# When a user has this GID he can become an Admin for webadmininterface
webadminAdminGid=1000
```

To see all webadmin specific property values have a look at `/usr/share/dcache/defaults/webadmin.properties`. For information on gPlazma configuration have a look at Chapter 12, *Authorization in dCache* and for a special example the section called “gPlazma config example to work with authenticated webadmin”. After startup of webadmin you can reach it via `http://example.com:8080/webadmin`. Since webadmin bases on the `info` it takes some time until all values are populated, because `info` needs to collect them first. It is recommended to let `info` run on the same machine then Webadmin.
Chapter 17. ACLs in dCache

Irina Kozlova
Paul Millar

Starting with the 1.9.3 series, dCache includes support for Access Control Lists (ACLs). This support is conforming to the NFS version 4 Protocol specification [http://www.nfsv4-editor.org/draft-25/draft-ietf-nfsv4-minorversion1-25.html].

This chapter provides some background information and details on configuring dCache to use ACLs and how to administer the resulting system.

ACLs and pnfs

ACLs are only supported with the Chimera name space backend. Versions before 1.9.12 had partial support for ACLs with the pnfs backend, however due to the limitations of that implementation ACLs were practically useless with pnfs.

Introduction

dCache allows control over namespace operations (e.g., creating new files and directories, deleting items, renaming items) and data operations (reading data, writing data) using the standard Unix permission model. In this model, files and directories have both owner and group-owner attributes and a set of permissions that apply to the owner, permissions for users that are members of the group-owner group and permissions for other users.

Although Unix permission model is flexible enough for many deployment scenarios there are configurations that either cannot configured easily or are impossible. To satisfy these more complex permission handling dCache has support for ACL-based permission handling.

An Access Control List (ACL) is a set of rules for determining whether an end-user is allowed to undertake some specific operation. Each ACL is tied to a specific namespace entry: a file or directory. When an end-user wishes to undertake some operation then the ACL for that namespace entry is checked to see if that user is authorised. If the operation is to create a new file or directory then the ACL of the parent directory is checked.

File- and directory- ACLs

Each ACL is associated with a specific file or directory in dCache. Although the general form is the same whether the ACL is associated with a file or directory, some aspects of an ACL may change. Because of this, we introduce the terms file-ACL and directory-ACL when taking about ACLs associated with a file or a directory respectively. If the term ACL is used then it refers to both file-ACLs and directory-ACLs.

Each ACL contains a list of one or more Access Control Entries (ACEs). The ACEs describe how dCache determines whether an end-user is authorised. Each ACE contains information about which group of end users it applies to and describes whether this group is authorised for some subset of possible operations.

The order of the ACEs within an ACL is significant. When checking whether an end-user is authorised each ACE is checked in turn to see if it applies to the end-user and the requested operation. If it does then that ACE determines whether that end-user is authorised. If not then the next ACE is checked. Thus an ACL can have several ACEs and the first matched ACE “wins”.

147
One of the problems with traditional Unix-based permission model is its inflexible handling of newly created files and directories. With transitional filesystems, the permissions that are set are under the control of the user-process creating the file. The sysadmin has no direct control over the permissions that newly files or directories will have. The ACL permission model solves this problem by allowing explicit configuration using inheritance.

ACL inheritance is when a new file or directory is created with an ACL containing a set of ACEs from the parent directory’s ACL. The inherited ACEs are specially marked so that only those that are intended will be inherited.

Inheritance only happens when a new file or directory is created. After creation, the ACL of the new file or directory is completely decoupled from the parent directory’s ACL: the ACL of the parent directory may be altered without affecting the ACL of the new file or directory and visa versa.

Inheritance is optional. Within a directory’s ACL some ACEs may be inherited whilst others are not. New files or directories will receive only those ACEs that are configured; the remaining ACEs will not be copied.

**Database configuration**

ACL support requires database tables to store ACL and ACE information. These tables are part of the Chimera name space backend and for a new installation no additional steps are needed to prepare the database.

Early versions of Chimera (before dCache 1.9.3) did not create the ACL table during installation. If the database is lacking the extra table then it has to be created before enabling ACL support. This is achieved by applying two SQL files:

```
[root] # psql chimera < /usr/share/dcache/chimera/sql/addACLtoChimeraDB.sql
[root] # psql chimera < /usr/share/dcache/chimera/sql/pgsql-procedures.sql
```

**Configuring ACL support**

The `dcache.conf` and layout files contain a number of settings that may be adjusted to configure dCache’s permission settings. These settings are are described in this section.

**Enabling ACL support**

To enable ACL support set the property `aclEnabled` to `true`. This property applies to the `pnfs-manager` and `acl` services and only need to be defined for these services.

**Enabling the acl service**

To query and define ACLs on files and directories enable the `acl` service. This service exposes a command line interface to administer ACLs. The command line interface of the service is described in section the section called “Administrating ACLs”.

To enable the `acl` service, you have to change the layout file corresponding to your dCache-instance. Enable the `acl` service within the domain that you want to run it in by adding the following line

```
.. [domainName/acl]
```
ACLs in dCache

Administrating ACLs

Altering dCache ACL behaviour is achieved by connecting to the acladmin well-known cell using the administrator interface. For further details about how to use the administrator interface, see the section called “The Admin Interface”.

The info and help commands are available within acladmin and fulfil their usual functions.

How to set ACLs

The setfacl command is used to set a new ACL. This command accepts arguments with the following form:

```
setfacl ID ACE [ACE...]
```

The ID argument is either a pnfs-ID or the absolute path of some file or directory in dCache. The setfacl command requires one or more ACE arguments separated by spaces.

The setfacl command creates a new ACL for the file or directory represented by ID. This new ACL replaces any existing ACEs for ID.

An ACL has one or more ACEs. Each ACE defines permissions to access this resource for some Subject. The ACEs are space-separated and the ordering is significant. The format and description of these ACE values are described below.

Description of the ACE structure

The ACE arguments to the setfacl command have a specific format. This format is described below in Extended Backus-Naur Form (EBNF).

```
[1]   ACE : ::= Subject ':' Access |  
       Subject ':' Access ':' Inheritance  
[2]   Subject : ::= 'USER:' UserID |  
       'GROUP:' GroupID |  
       'OWNER@' |  
       'GROUP@' |  
       'EVERYONE@' |  
       'ANONYMOUS@' |  
       'AUTHENTICATED@'  
       '-' Mask  
       MaskItem  
[5]   MaskItem : ::= 'r' | 't' | 'w' | 'f' | 's' | 'a' | 'n' | 'N' | 'x' | 'd' | 'D' | 't' | 'T' |  
       'c' | 'C' | 'o'  
[6]   Inheritance : ::= Inheritance Flag |  
       Flag  
[7]   Flag : ::= 'f' | 'd' | 'o'  
[8]   UserID : ::= INTEGER  
[9]   GroupID : ::= INTEGER
```

The various options are described below.
The Subject

The Subject defines to which user or group of users the ACE will apply. It acts as a filter so that only those users that match the Subject will have their access rights affected.

As indicated by the EBNF above, the Subject of an ACE can take one of several forms. These are described below:

**USER:** id
- The `USER:` prefix indicates that the ACE applies only to the specific end-user: the dCache user with ID `id`. For example, `USER:0:+w` is an ACE that allows user 0 to write over a file's existing data.

**GROUP:** id
- The `GROUP:` prefix indicates that the ACE applies only to those end-users who are a member of the specific group: the dCache group with ID `id`. For example, `GROUP:20:+a` is an ACE that allows any user who is a member of group 20 to append data to the end of a file.

**OWNER@**
- The `OWNER@` subject indicates that the ACE applies only to whichever end-user owns the file or directory. For example, `OWNER@:+d` is an ACE that allows the file’s or directory’s owner to delete it.

**GROUP@**
- The `GROUP@` subject indicates that the ACE applies only to all users that are members of the group-owner of the file or directory. For example, `GROUP@:+l` is an ACE that allows any user that is in a directory’s group-owner to list the directory’s contents.

**EVERYONE@**
- The `EVERYONE@` subject indicates that the ACE applies to all users. For example, `EVERYONE@:+r` is an ACE that makes a file world-readable.

**ANONYMOUS@**
- The `ANONYMOUS@` Subject indicates that the ACE applies to all users who have not authenticated themselves. For example, `ANONYMOUS@:-l` is an ACE that prevents unauthenticated users from listing the contents of a directory.

**AUTHENTICATED@**
- The `AUTHENTICATED@` Subject indicates that an ACE applies to all authenticated users. For example, `AUTHENTICATED@:+r` is an ACE that allows any authenticated user to read a file’s contents.

**Authenticated or anonymous**

An end user of dCache is either authenticated or is unauthenticated, but never both. Because of this, an end user operation will either match ACEs with `ANONYMOUS@` Subjects or `AUTHENTICATED@` Subjects but the request will never match both at the same time.

Access mask

Access (defined in the ACE EBNF above) describes what kind of operations are being described by the ACE and whether the ACE is granting permission or denying it.

An individual ACE can either grant permissions or deny them, but never both. However, an ACL may be composed of any mixture of authorising- and denying- ACEs. The first character of Access describes whether the ACE is authorising or denying.

If Access begins with a plus symbol (+) then the ACE authorises the Subject some operations. The ACE `EVERYONE@:+r` authorises all users to read a file since the Access begins with a +.

If the Access begins with a minus symbol (−) then the ACE denies the Subject some operations. The ACE `EVERYONE@:−r` prevents any user from reading a file since the Access begins with a −.
The first character of Access must be + or −, no other possibility is allowed. The initial + or − of Access is followed by one or more operation letters. These letters form the ACE’s access mask (Mask in ACE EBNF above).

The access mask describes which operations may be allowed or denied by the ACE. Each type of operation has a corresponding letter; for example, obtaining a directory listing has a corresponding letter \( \mathbf{l} \). If a user attempts an operation of a type corresponding to a letter present in the access mask then the ACE may affect whether the operation is authorised. If the corresponding letter is absent from the access mask then the ACE will be ignored for this operation.

The following table describes the access mask letters and the corresponding operations:

**File- and directory-specific operations**

Some operations and, correspondingly, some access mask letters only make sense for ACLs attached to certain types of items. Some operations only apply to directories, some operations are only for files and some operations apply to both files and directories.

When configuring an ACL, if an ACE has an operation letter in the access mask that is not applicable to whatever the ACL is associated with then the letter is converted to an equivalent. For example, if \( \mathbf{l} \) (list directory) is in the access mask of an ACE that is part of a file-ACL then it is converted to \( \mathbf{r} \). These mappings are described in the following table.

- **r** reading data from a file. Specifying \( \mathbf{r} \) in an ACE’s access mask controls whether end-users are allowed to read a file’s contents. If the ACE is part of a directory-ACL then the letter is converted to \( \mathbf{l} \).

- **l** listing the contents of a directory. Specifying \( \mathbf{l} \) in an ACE’s access mask controls whether end-users are allowed to list a directory’s contents. If the ACE is part of a file-ACL then the letter is converted to \( \mathbf{r} \).

- **w** overwriting a file’s existing contents. Specifying \( \mathbf{w} \) in an ACE’s access mask controls whether end-users are allowed to write data anywhere within the file’s current offset range. This includes the ability to write to any arbitrary offset and, as a result, to grow the file. If the ACE is part of a directory-ACL then the letter is converted to \( \mathbf{f} \).

- **f** creating a new file within a directory. Specifying \( \mathbf{f} \) in an ACE’s access mask controls whether end-users are allowed to create a new file. If the ACE is part of a file-ACL then then the letter is converted to \( \mathbf{w} \).

- **s** creating a subdirectory within a directory. Specifying \( \mathbf{s} \) in an ACE’s access mask controls whether end-users are allowed to create new subdirectories. If the ACE is part of a file-ACL then the letter is converted to \( \mathbf{a} \).

- **a** appending data to the end of a file. Specifying \( \mathbf{a} \) in an ACE’s access mask controls whether end-users are allowed to add data to the end of a file. If the ACE is part of a directory-ACL then the letter is converted to \( \mathbf{s} \).

- **n** reading attributes. Specifying \( \mathbf{n} \) in an ACE’s access mask controls whether end-users are allowed to read attributes. This letter may be specified in ACEs that are part of a file-ACL and those that are part of a directory-ACL.

- **N** write attributes. Specifying \( \mathbf{N} \) in an ACE’s access mask controls whether end-users are allowed to write attributes. This letter may be specified in ACEs that are part of a file-ACL and those that are part of a directory-ACL.
ACLs in dCache

× executing a file or entering a directory. × may be specified in an ACE that is part of a file-ACL or a directory-ACL; however, the operation that is authorised will be different.

Specifying × in an ACEs access mask that is part of a file-ACL will control whether end users matching the ACE Subject are allowed to execute that file.

Specifying × in an ACEs access mask that is part of a directory-ACL will control whether end users matching ACE Subject are allowed to search a directory for a named file or subdirectory. This operation is needed for end users to change their current working directory.

c deleting a namespace entry. Specifying c in an ACE’s access mask controls whether end-users are allowed to delete the file or directory the ACL is attached. The end user must be also authorised for the parent directory (see D).

D deleting a child of a directory. Specifying D in the access mask of an ACE that is part of a directory-ACL controls whether end-users are allowed to delete items within that directory. The end user must be also authorised for the existing item (see d).

t reading basic attributes. Specifying t in the access mask of an ACE controls whether end users are allowed to read basic (i.e., non-ACL) attributes of that item.

T altering basic attributes. Specifying T in an ACE’s access mask controls whether end users are allowed to alter timestamps of the item the ACE’s ACL is attached.

c reading ACL information. Specifying c in an ACE’s access mask controls whether end users are allowed to read the ACL information of the item to which the ACE’s ACL is attached.

C writing ACL information. Specifying C in an ACE’s access mask controls whether end users are allowed to update ACL information of the item to which the ACE’s ACL is attached.

o altering owner and owner-group information. Specifying o controls whether end users are allowed to change ownership information of the item to which the ACE’s ACL is attached.

ACL inheritance

To enable ACL inheritance, the optional inheritance flags must be defined. The flag is a list of letters. There are three possible letters that may be included and the order doesn’t matter.

ACE Inheritance Flags

f This inheritance flag only affects those ACEs that form part of an directory-ACL. If the ACE is part of a file-ACL then specifying f has no effect.

If a file is created in a directory with an ACE with f in inheritance flags then the ACE is copied to the newly created file’s ACL. This ACE copy will not have the f inheritance flag.

Specifying f in an ACE’s inheritance flags does not affect whether this ACE is inherited by a newly created subdirectory. See d for more details.

d This inheritance flag only affect those ACEs that form part of an directory-ACL. If the ACE is part of a file-ACL then specifying d has no effect.

Specifying d in an ACE’s inheritance flags does not affect whether this ACE is inherited by a newly created file. See f for more details.
If a subdirectory is created in a directory with an ACE with $d$ in the ACE’s inheritance flag then the ACE is copied to the newly created subdirectory’s ACL. This ACE copy will have the $d$ inheritance flag specified. If the $f$ inheritance flag is specified then this, too, will be copied.

- The $o$ flag may only be used when the ACE also has the $f$, $d$ or both $f$ and $d$ inheritance flags.

Specifying $o$ in the inheritance flag will suppress the ACE. No user operations will be authorised or denied as a result of such an ACE.

When a file or directory inherits from an ACE with $o$ in the inheritance flags then the $o$ is not present in the newly created file or directory’s ACE. Since the newly created file or directory will not have the $o$ in its inheritance flags the ACE will take effect.

An $o$ in the inheritance flag allows child files or directories to inherit authorisation behaviour that is different from the parent directory.

**Examples**

This section gives some specific examples of how to set ACLs to achieve some specific behaviour.

**Example 17.1. ACL allowing specific user to delete files in a directory**

This example demonstrates how to configure a directory-ACL so user 3750 can delete any file within the directory `/pnfs/example.org/data/exampleDir`.

```bash
(acladmin) admin > setfacl /pnfs/example.org/data/exampleDir EVERYONE@:+l USER:3750:D
(...line continues...) USER:3750:+d:of
(acladmin) admin > setfacl /pnfs/example.org/data/exampleDir/existingFile1
(...line continues...) USER:3750:+d:f
(acladmin) admin > setfacl /pnfs/example.org/data/exampleDir/existingFile2
(...line continues...) USER:3750:+d:f
```

The first command creates an ACL for the directory. This ACL has three ACEs. The first ACE allows anyone to list the contents of the directory. The second ACE allows user 3750 to delete content within the directory in general. The third ACE is inherited by all newly created files and specifies that user 3750 is authorised to delete the file independent of that file’s ownership.

The second and third commands creates an ACL for files that already exists within the directory. Since ACL inheritance only applies to newly created files or directories, any existing files must have an ACL explicitly set.
Example 17.2. ACL to deny a group

The following example demonstrates authorising all end users to list a directory. Members of group 1000 can also create subdirectories. However, any member of group 2000 can do neither.

```
(acladmin) admin > setfacl /pnfs/example.org/data/exampleDir GROUP:2000:-sl EVERYONE@:+l GROUP:1000:+s

EVERYONE@:+l GROUP:1000:+s
```

The first ACE denies any member of group 2000 the ability to create subdirectories or list the directory contents. As this ACE is first, it takes precedence over other ACEs.

The second ACE allows everyone to list the directory’s content. If an end user who is a member of group 2000 attempts to list a directory then their request will match the first ACE so will be denied. End users attempting to list a directory that are not a member of group 2000 will not match the first ACE but will match the second ACE and will be authorised.

The final ACE authorises members of group 1000 to create subdirectories. If an end user who is a member of group 1000 and group 2000 attempts to create a subdirectory then their request will match the first ACE and be denied.

Example 17.3. ACL to allow a user to delete all files and subdirectories

This example is an extension to Example 17.1, “ACL allowing specific user to delete files in a directory”. The previous example allowed deletion of the contents of a directory but not the contents of any subdirectories. This example allows user 3750 to delete all files and subdirectories within the directory.

```
(acladmin) admin > setfacl /pnfs/example.org/data/exampleDir USER:3750:+D:d USER:3750:+d:odf

USER:3750:+D:d USER:3750:+d:odf
```

The first ACE is USER:3750:+D:d. This authorises user 3750 to delete any contents of directory /pnfs/example.org/data/exampleDir that has an ACL authorising them with d operation.

The first ACE also contains the inheritance flag d so newly created subdirectories will inherit this ACE. Since the inherited ACE will also contain the d inheritance flag, this ACE will be copied to all subdirectories when they are created.

The second ACE is USER:3750:+d:odf. The ACE authorises user 3750 to delete whichever item the ACL containing this ACE is associated with. However, since the ACE contains the o in the inheritance flags, user 3750 is not authorised to delete the directory /pnfs/example.org/data/exampleDir

Since the second ACE has both the d and f inheritance flags, it will be inherited by all files and subdirectories of /pnfs/example.org/data/exampleDir, but without the o flag. This authorises user 3750 to delete these items.

Subdirectories (and files) will inherit the second ACE with both d and f inheritance flags. This implies that all files and sub-subdirectories within a subdirectory of /pnfs/example.org/data/exampleDir will also inherit this ACE, so will also be deletable by user 3750.

Viewing configured ACLs

The `getfacl` is used to obtain the current ACL for some item in dCache namespace. It takes the following arguments.
getfacl [pnfsId] [globalPath]

The getfacl command fetches the ACL information of a namespace item (a file or directory). The item may be specified by its pnfs-ID or its absolute path.

Example 17.4. Obtain ACL information by absolute path

```
(acladmin) admin > getfacl /pnfs/example.org/data/exampleDir
ACL: rsId = 00004EEFE7E59A344A1998E74480088A54, rsType = DIR
   order = 0, type = A, accessMsk = lfsD, who = USER, whoID = 12457
   order = 1, type = A, flags = f, accessMsk = lfd, who = USER, whoID = 87552
In extra format:
USER:12457:+lfsD
USER:87552:+lfd:f
```

The information is provided twice. The first part gives detailed information about the ACL. The second part, after the In extra format: heading, provides a list of ACEs that may be used when updating the ACL using the setfacl command.
Chapter 18. GLUE Info Provider

The GLUE information provider supplied with dCache provides the information about the dCache instance in a standard format called GLUE. This is necessary so that WLCG infrastructure (such as FTS) and clients using WLCG tools can discover the dCache instance and use it correctly.

The process of configuring the info-provider is designed to have the minimum overhead so you can configure it manually; however, you may prefer to use an automatic configuration tool, such as YAIM.

**Note**

Be sure you have at least v2.0.8 of glue-schema RPM installed on the node running the info-provider.

This chapter describes how to enable and test the dCache-internal collection of information needed by the info-provider. It also describes how to configure the info-provider and verify that it is working correctly. Finally, it describes how to publish this information within BDII, verify that this is working and troubleshoot any problems.

**Warning**

Please be aware that changing information provider may result in a brief interruption to published information. This may have an adverse affect on client software that make use of this information.

**Internal collection of information**

The info-provider takes as much information as possible from dCache. To achieve this, it needs the internal information-collecting service, info, to be running and a means to collect that information: httpd. Make sure that both the httpd and info services are running within your dCache instance. By default, the info service is started on the admin-node; but it is possible to configure dCache so it runs on a different node. You should run only one info service per dCache instance.

The traditional (pre-1.9.7) allocation of services to domains has the info cell running in the infoDomain domain. A dCache system that has been migrated from this old configuration will have the following fragment in the node’s layout file:

```
[infoDomain]
[infoDomain/info]
```

It is also possible to run the info service inside a domain that runs other services. The following example show the information domain that hosts the admin, httpd, topo and info services.

```
[information]
[information/admin]
[information/httpd]
[information/topo]
[information/info]
```

For more information on configuring dCache layout files, see the section called “Defining domains and services”.

Use the dcache services command to see if a particular node is configured to run the info service. The following shows the output if the node has an information domain that is configured to run the info cell.
If a node has no domain configured to host the info service then the above dcache services command will give no output:

[root] # dcache services | grep info
information info        info               /var/log/dCache/information.log

If no running domain within any node of your dCache instance is running the info service then you must add the service to a domain and restart that domain.

In this example, the info service is added to the example domain. Note that the specific choice of domain (example) is just to give a concrete example; the same process may be applied to a different domain.

The layouts file for this node includes the following definition for the example domain:

```
[example]
[example/admin]
[example/httpd]
[example/topo]
```

By adding the extra line [example/info] to the layouts file, in future, the example domain will host the info service.

```
[example]
[example/admin]
[example/httpd]
[example/topo]
[example/info]
```

To actually start the info cell, the example domain must be restarted.

[root] # dcache restart example
Stopping example (pid=30471) 0 done
Starting example done

With the example domain restarted, the info service is now running.

You can also verify both the httpd and info services are running using the wget command. The specific command assumes that you are logged into the node that has the httpd service (by default, the admin node). You may run the command on any node by replacing localhost with the hostname of the node running the httpd service.

The following example shows the output from the wget when the info service is running correctly:

```bash
--17:57:38--  http://localhost:2288/info
Resolving localhost... 127.0.0.1
Connecting to localhost|127.0.0.1|:2288... connected.
HTTP request sent, awaiting response... 200 Document follows
Length: 372962 (364K) [application/xml]
Saving to: `/dev/null'
100%[===========================================================================] 372,962 --.-K/s   in 0.001s
17:57:38 (346 MB/s) - `'/dev/null' saved [372962/372962]
```
If the `httpd` service isn’t running then the command will generate the following output:

```
--10:05:35--  http://localhost:2288/info
 => `/dev/null'
Resolving localhost... 127.0.0.1
Connecting to localhost|127.0.0.1|:2288... failed: Connection refused.
```

To fix the problem, ensure that the `httpd` service is running within your dCache instance. This is the service that provides the web server monitoring within dCache. To enable the service, follow the same procedure for enabling the info cell, but add the `httpd` service within one of the domains in dCache.

If running the `wget` command gives an error message with `Unable to contact the info cell. Please ensure the info cell is running`:

```
--10:03:13--  http://localhost:2288/info
 => `/dev/null'
Resolving localhost... 127.0.0.1
Connecting to localhost|127.0.0.1|:2288... connected.
HTTP request sent, awaiting response... 503 Unable to contact the info cell. Please ensure the info cell is running.
10:03:13 ERROR 503: Unable to contact the info cell. Please ensure the info cell is running.
```

This means that the info service is not running. Follow the instructions for starting the info service given above.

**Configuring the info provider**

In the directory `/etc/dcache` you will find the file `info-provider.xml`. This file is where you configure the info-provider. It provides information that is difficult or impossible to obtain from the running dCache directly.

You must edit the `info-provider.xml` to customise its content to match your dCache instance. In some places, the file contains place-holder values. These place-holder values must be changed to the correct values for your dCache instance.

**Careful with `<` and `&` characters**

Take care when editing the `info-provider.xml` file! After changing the contents, the file must remain valid, well-formed XML. In particular, be very careful when writing a less-than symbol (`<`) or an ampersand symbol (`&`).

- Only use an ampersand symbol (`&`) if it is part of an entity reference. An entity reference is a sequence that starts with an ampersand symbol and is terminated with a semi-colon (`;`), for example `&gt;` and `&apos;` are entity markups.

  If you want to include an ampersand character in the text then you must use the `&amp;` entity; for example, to include the text “me & you” the XML file would include `me &amp; you`.

- Only use a less-than symbol (`<`) when starting an XML element; for example, `<constant id="TEST">A test value</constant>`.

  If you want to include a less-than character in the text then you must use the `&lt;` entity; for example, to include the text “l < 2” the XML file would include `l &lt; 2`. 

158
The following example shows the SE-NAME constant (which provides a human-readable description of the dCache instance) from a well-formed info-provider.xml configuration file:

```xml
<constant id="SE-NAME">Simple & small dCache instance for small VOs (typically < 20 users)</constant>
```

The SE-NAME constant is configured to have the value “Simple & small dCache instance for small VOs (typically < 20 users)”. This illustrates how to include ampersand and less-than characters in an XML file.

When editing the info-provider.xml file, you should only edit text between two elements or add more elements (for lists and mappings). You should never alter the text inside double-quote marks.

This example shows how to edit the SITE-UNIQUE-ID constant. This constant has a default value EXAMPLESITE-ID, which is a place-holder value and must be edited.

```xml
<constant id="SITE-UNIQUE-ID">EXAMPLESITE-ID</constant>
```

To edit the constant’s value, you must change the text between the start- and end-element tags: EXAMPLESITE-ID. You should not edit the text SITE-UNIQUE-ID as it is in double-quote marks. After editing, the file may read:

```xml
<constant id="SITE-UNIQUE-ID">DESY-HH</constant>
```

The info-provider.xml contains detailed descriptions of all the properties that are editable. You should refer to this documentation when editing the info-provider.xml.

**Testing the info provider**

Once you have configured info-provider.xml to reflect your site’s configuration, you may test that the info provider produces meaningful results.

Running the info-provider script should produce GLUE information in LDIF format; for example:

```
[root] # dcache-info-provider | head -20
# LDIF generated by Xylophone v0.2
# XSLT processing using Saxon 6.5.5 from Michael Kay 1 (http://saxon.sf.net)
# at: 2011-05-11T14:08:45+02:00

dn: GlueSEUniqueID=dcache-host.example.org,mds-vo-name=resource,o=grid
objectClass: GlueSETop
objectClass: GlueSE
objectClass: GlueKey
objectClass: GlueSchemaVersion
GlueSEStatus: Production
GlueSEUniqueID: dcache-host.example.org
GlueSEImplementationName: dCache
GlueSEArchitecture: multidisk
GlueSEImplementationVersion: 1.9.12-3 (ns=Chimera)
GlueSESizeTotal: 86
```

The actual values you see will be site-specific and depend on the contents of the info-provider.xml file and your dCache configuration.
To verify that there are no problems, redirect standard-out to /dev/null to show only the error messages:

```
[root] # dcache-info-provider >/dev/null
```

If you see error messages (which may be repeated several times) of the form:

```
[root] # dcache-info-provider >/dev/null
Recoverable error
Failure reading http://localhost:2288/info: no more input
```

then it is likely that either the httpd or info service has not been started. Use the above `wget` test to check that both services are running. You can also see which services are available by running the `dcache services` and `dcache status` commands.

## Decommissioning the old info provider

Sites that were using the old (pre-1.9.5) info provider should ensure that there are no remnants of this old info-provider on their machine. Although the old info-provider has been removed from dCache, it relied on static LDIF files, which might still exist. If so, then BDII will obtain some information from the current info-provider and some out-of-date information from the static LDIF files. BDII will then attempt to merge the two sources of information. The merged information may provide a confusing description of your dCache instance, which may prevent clients from working correctly.

The old info provider had two static LDIF files and a symbolic link for BDII. These are:

- The file `lcg-info-static-SE.ldif`,
- The file `lcg-info-static-dSE.ldif`,
- The symbolic link `/opt/glite/etc/gip/plugin`, which points to `/opt/d-cache/jobs/infoDynamicSE-plugin-dcache`.

The two files (`lcg-info-static-SE.ldif` and `lcg-info-static-dSE.ldif`) appear in the `/opt/lcg/var/gip/ldif` directory; however, it is possible to alter the location BDII will use. In BDII v4, the directory is controlled by the `static_dir` variable (see `/opt/glite/etc/gip/glite-info-generic.conf` or `/opt/lcg/etc/lcg-info-generic.conf`). For BDII v5, the `BDII_LDIF_DIR` variable (defined in `/opt/bdii/etc/bdii.conf`) controls this behaviour.

You must delete the above three entries: `lcg-info-static-SE.ldif`, `lcg-info-static-dSE.ldif` and the plugin symbolic link.

The directory with the static LDIF, `/opt/lcg/var/gip/ldif` or `/opt/glite/etc/gip/ldif` by default, may contain other static LDIF entries that are relics of previous info-providers. These may have filenames like `static-file-SE.ldif`.

Delete any static LDIF file that contain information about dCache. With the info-provider, all LDIF information comes from the info-provider; there should be no static LDIF files. Be careful not to delete any static LDIF files that come as part of BDII; for example, the `default.ldif` file, if present.

## Publishing dCache information

BDII obtains information by querying different sources. One such source of information is by running an info-provider command and taking the resulting LDIF output. To allow BDII to obtain dCache infor-
GLUE Info Provider

mation, you must allow BDII to run the dCache info-provider. This is achieved by symbolically linking the dcache-info-provider script into the BDII plugins directory:

```
[root] # ln -s /usr/sbin/dcache-info-provider 
/opt/glite/etc/gip/provider/
```

If the BDII daemons are running, then you will see the information appear in BDII after a short delay; by default this is (at most) 60 seconds.

You can verify that information is present in BDII by querying BDII using the `ldapsearch` command. Here is an example that queries for GLUE v1.3 objects:

```
[root] # ldapsearch -LLL -x -H ldap://dcache-host:2170 -b o=grid 
' '(objectClass=GlueSE)' 

dn: GlueSEUniqueID=dcache-host.example.org,Mds-Vo-name=resource,o=grid 
GlueSEStatus: Production 
objectClass: GlueSETop 
objectClass: GlueSE 
objectClass: GlueKey 
objectClass: GlueSchemaVersion 
GlueSETotalNearlineSize: 0 
GlueSETopArchitecture: multidisk 
GlueSchemaVersionMinor: 3 
GlueUSEnabledNearlineSize: 0 
GlueChunkKey: GlueSEUniqueID=dcache-host.example.org 
GlueForeignKey: GlueSiteUniqueID=example.org 
GlueSchemaVersionMajor: 1 
GlueSEImplementationName: dCache 
GlueSEUniqueID: dcache-host.example.org 
GlueSEImplementationVersion: 1.9.12-3 (ns=Chimera) 
GlueSESizeFree: 84 
GlueSEUnitOnlineSize: 2 
GlueSETotalOnlineSize: 86 
GlueSESizeTotal: 86
```

**Careful with the hostname**

You must replace `dcache-host` in the URI `ldap://dcache-host:2170/` with the actual hostname of your node.

It’s tempting to use `localhost` in the URI when executing the `ldapsearch` command; however, BDII binds to the ethernet device (e.g., eth0). Typically, `localhost` is associated with the loopback device (lo), so querying BDII with the URI `ldap://localhost:2170/` will fail.

The LDAP query uses the `o=grid` object as the base; all reported objects are descendant objects of this base object. The `o=grid` base selects only the GLUE v1.3 objects. To see GLUE v2.0 objects, the base object must be `o=glue`.

The above `ldapsearch` command queries BDII using the `(objectClass=GlueSE)` filter. This filter selects only objects that provide the highest-level summary information about a storage-element. Since each storage-element has only one such object and this BDII instance only describes a single dCache instance, the command returns only the single LDAP object.

To see all GLUE v1.3 objects in BDII, repeat the above `ldapsearch` command but omit the `(objectClass=GlueSE)` filter: `ldapsearch -LLL -x -H ldap://dcache-host:2170 -b o=grid`. This command will output all GLUE v1.3 LDAP objects, which includes all the GLUE v1.3 objects from the info-provider.

Searching for all GLUE v2.0 objects in BDII is achieved by repeating the above `ldapsearch` command but omitting the `(objectClass=GlueSE)` filter and changing the search base to `o=glue:`
ldapsearch -LLL -x -H ldap://dcache-host:2170 -b o=glue. This command returns a completely different set of objects from the GLUE v1.3 queries.

You should be able to compare this output with the output from running the info-provider script manually: BDII should contain all the objects that the dCache info-provider is supplying. Unfortunately, the order in which the objects are returned and the order of an object’s properties is not guaranteed; therefore a direct comparison of the output isn’t possible. However, it is possible to calculate the number of objects in GLUE v1.3 and GLUE v2.0.

First, calculate the number of GLUE v1.3 objects in BDII and compare that to the number of GLUE v1.3 objects that the info-provider supplies.

```
[root] # ldapsearch -LLL -x -H ldap://dcache-host:2170 -b o=grid \  
'(objectClass=GlueSchemaVersion)' | grep ^dn | wc -l
10
[root] # dcache-info-provider | \  
grep -i "objectClass: GlueSchemaVersion" | wc -l
10
```

Now calculate the number of GLUE v2.0 objects in BDII describing your dCache instance and compare that to the number provided by the info-provider:

```
[root] # ldapsearch -LLL -x -H ldap://dcache-host:2170 -b o=glue | perl -p00e 's/
 //g' | \  
grep dn.*GLUE2ServiceID | wc -l
27
[root] # dcache-info-provider | perl -p00e 's/
 //g' | \  
grep ^dn.*GLUE2ServiceID | wc -l
27
```

If there is a discrepancy in the pair of numbers obtained in the above commands then BDII has rejecting some of the objects. This is likely due to malformed LDAP objects from the info-provider.

## Troubleshooting BDII problems

The BDII log file should explain why objects are not accepted; for example, due to a badly formatted attribute. The default location of the log file is /var/log/bdii/bdii-update.log, but the location is configured by the BDII_LOG_FILE option in the /opt/bdii/etc/bdii.conf file.

The BDII log files may show entries like:

```
2011-05-11 04:04:58,711: [WARNING] additional info: objectclass: value #1 invalid per syntax
```

This problem comes when BDII is attempting to inject new information. Unfortunately, the information isn’t detailed enough for further investigation. To obtain more detailed information from BDII, switch the BDII_LOG_LEVEL option in /opt/bdii/etc/bdii.conf to DEBUG. This will provide more information in the BDII log file.

Logging at DEBUG level has another effect; BDII no longer deletes some temporary files. These temporary files are located in the directory controlled by the BDII_VAR_DIR option. This is /var/run/bdii by default.

There are several temporary files located in the /var/run/bdii directory. When BDII decides which objects to add, modify and remove, it creates LDIF instructions inside temporary files add.ldif, modify.ldif and delete.ldif respectively. Any problems in the attempt to add, modify and
delete LDAP objects are logged to corresponding error files: errors with add.ldif are logged to add.err, modify.ldif to modify.err and so on.

Once information in BDII has stabilised, the only new, incoming objects for BDII come from those objects that it was unable to add previously. This means that add.ldif will contain these badly formatted objects and add.err will contain the corresponding errors.

**Updating information**

The information contained within the info service may take a short time to achieve a complete overview of dCache’s state. For certain gathered information it may take a few minutes before the information stabilises. This delay is intentional and prevents the gathering of information from adversely affecting dCache’s performance.

The information presented by the LDAP server is updated periodically by BDII requesting fresh information from the info-provider. The info-provider obtains this information by requesting dCache’s current status from info service. By default, BDII will query the info-provider every 60 seconds. This will introduce an additional delay between a change in dCache’s state and that information propagating.

Some information is hard-coded within the info-provider.xml file; that is, you will need to edit this file before the published value(s) will change. These values are ones that typically a site-admin must choose independently of dCache’s current operations.
Chapter 19. Stage Protection

Irina Kozlova

A dCache system administrator may specify a list of DN/FQANs which are allowed to trigger tape restores for files not being available on disk. Users, requesting tape-only files, and not being on that white list, will receive a permission error and no tape operation is launched. Stage protection can be enhanced to allow authorization specific to a dCache storage group. The additional configuration parameter is optional allowing the stage protection to be backwards compatible when stage authorization is not specific to a storage group.

Configuration of Stage Protection

Stage protection can optionally be configured in the poolmanager rather than on the doors and the pinmanager. Thus the white list needs to be present on a single node only. To enable this, define the following parameter in /etc/dcache/dcache.conf:

```
stagePolicyEnforcementPoint=PoolManager
```

The file name of the white list must be configured by setting the stageConfigurationFilePath parameter in /etc/dcache/dcache.conf:

```
stageConfigurationFilePath=/etc/dcache/StageConfiguration.conf
```

The parameter needs to be defined on all nodes which enforce the stage protection, i.e., either on the doors and the pinmanager, or in the poolmanager depending on the stage policy enforcement point.

Definition of the White List

The Stage Configuration File will contain a white list. Each line of the white list may contain up to three regular expressions enclosed in double quotes. The regular expressions match the DN, FQAN, and the Storage Group written in the following format:

"DN" ["FQAN"] ["StorageGroup"]

Lines starting with a hash symbol # are discarded as comments.

The regular expression syntax follows the syntax defined for the Java Pattern class [http://java.sun.com/javase/6/docs/api/java/util/regex/Pattern.html].

Here are some examples of the White List Records:

```
".*" "/atlas/Role=production"
"/C=DE/O=DESY/CN=Kermit the frog"
"/C=DE/O=DESY/CN=Beaker" "/desy"
"/O=GermanGrid/.*" "/desy/Role=.*"
```

This example authorizes a number of different groups of users:

- Any user with the FQAN /atlas/Role=production.
- The user with the DN /C=DE/O=DESY/CN=Kermit the frog, irrespective of which VOMS groups he belongs to.
• The user with the DN /C=DE/O=DESY/CN=Beaker but only if he is also identified as a member of VO desy (FQAN /desy)

• Any user with DN and FQAN that match /O=GermanGrid/.* and /desy/Role=.* respectively.

If a storage group is specified all three parameters must be provided. The regular expression ".*" may be used to authorize any DN or any FQAN. Consider the following example:

```
".*" /atlas/Role=production" "h1:raw@osm"
"/C=DE/O=DESY/CN=Scooter" ".*" "sql:chimera@osm"
```

In the example above:

• Any user with FQAN /atlas/Role=production is allowed to stage files located in the storage group h1:raw@osm.

• The user /C=DE/O=DESY/CN=Scooter, irrespective of which VOMS groups he belongs to, is allowed to stage files located in the storage group sql:chimera@osm.

With the plain dCap protocol the DN and FQAN are not known for any users.

In order to allow all dCap users to stage files the white list should contain the following record:

```
"**" "**"
```

In case this line is commented or not present in the white list, all dCap users will be disallowed to stage files.

It is possible to allow all dCap users to stage files located in a certain storage group.

In this example, all dCap users are allowed to stage files located in the storage group h1:raw@osm:

```
"**" "h1:raw@osm"
```

Chapter 20. dCache Clients.

Owen Synge

There are many client tools for dCache. These can most easily be classified by communication protocol.

**GSI-FTP**

dCache provides a GSI-FTP door, which is in effect a GSI authenticated FTP access point to dCache

**Listing a directory**

To list the content of a dCache directory, the GSI-FTP protocol can be used;

```
[user] $ edg-gridftp-ls gsiftp://gridftp-door.example.org/pnfs/example.org/data/dteam/
```

**Checking a file exists**

To check the existence of a file with GSI-FTP.

```
[user] $ edg-gridftp-exists gsiftp://gridftp-door.example.org/pnfs/example.org/data/dteam/
filler_test20050819130209790873000
[user] $ echo $?
0
[user] $ edg-gridftp-exists gsiftp://gridftp-door.example.org/pnfs/example.org/data/dteam/
filler_test200508191302097908730002
error the server sent an error response: 451 451 /pnfs/example.org/data/dteam/filler_test200508191302097908730002 not found
[user] $ echo $?
1
```

**Use the return code**

Please note the `echo $?` show the return code of the last run application. The error message returned from the client this should not be scripted against as it is one of many possible errors.

**Deleting files**

To delete files with GSI-FTP use the `edg-gridftp-rm` command.

```
[user] $ edg-gridftp-rm gsiftp://gridftp-door.example.org/pnfs/example.org/data/dteam/
filler_test20050811160948926780000
```

This deletes the file `filler_test20050811160948926780000` from the `/pnfs/example.org/data/dteam` using the door running on the host `gridftp-door.example.org` within the dCache cluster `example.org`

**Copying files**

globus-url-copy [[command line options]] [srcUrl] [destinationUrl]...

Copying file with `globus-url-copy` follows the syntax source, destination.
The following example copies the file /etc/group into dCache as the file /pnfs/example.org/data/dteam/test_GlobusUrlCopy.clinton.504.22080.20071102160121.2

```
[user] $ globus-url-copy 
file:///etc/group 
gsiftp://gridftp-door.example.org/pnfs/example.org/data/dteam/test_GlobusUrlCopy.clinton.504.22080.20071102160121.2
```

Please note that the five slashes are really needed.

**dCap**

When using **dccp** client or using the interposition library the errors Command failed! can be safely ignored.

**dccp**

The following example shows **dccp** being used to copy the file /etc/group into dCache as the file /pnfs/example.org/data/dteam/test6. The **dccp** program will connect to dCache without authenticating.

```
[user] $ /opt/d-cache/dcap/bin/dccp /etc/group dcap://dcap-door.example.org:22125/pnfs/example.org/data/dteam/test6
Command failed!
Server error message for [1]: "path /pnfs/example.org/data/dteam/test6 not found" (errno 10001).
597 bytes in 0 seconds
```

The following example shows **dccp** being used to upload the file /etc/group. In this example, **dccp** will authenticate with dCache using the GSI protocol.

```
[user] $ /opt/d-cache/dcap/bin/dccp /etc/group gsidcap://gsidcap-door.example.org:22128/pnfs/example.org/data/dteam/test5
Command failed!
Server error message for [1]: "path /pnfs/example.org/data/dteam/test5 not found" (errno 10001).
597 bytes in 0 seconds
```

The following example shows **dccp** with the debugging enabled. The value 63 controls how much information is displayed.

```
[user] $ /opt/d-cache/dcap/bin/dccp -d 63 /etc/group dcap://dcap-door.example.org:22128/pnfs/example.org/data/dteam/test3
Dcap Version version-1-2-42 Jul 10 2007 19:56:02
Using system native stat64 for /etc/group.
Allocated message queues 0, used 0
Using environment variable as configuration
Allocated message queues 1, used 1
Creating a new control connection to dcap-door.example.org:22128.
Activating IO tunnel. Provider: [libgsiTunnel.so].
Added IO tunneling plugin libgsiTunnel.so for dcap-door.example.org:22128.
Setting IO timeout to 20 seconds.
Connected in 0.00s.
Removing IO timeout handler.

Sending control message: 1 0 client stat "dcap://dcap-door.example.org:22128/pnfs/example.org/data/dteam/test3" -uid=501
Command failed!
Server error message for [1]: "path //pnfs/example.org/data/dteam/test3 not found" (errno 10001).
```
dCache Clients.

[1] unplugging node
Removing unneeded queue [1]
[1] destroing node
Real file name: /etc/group.
Using system native open for /etc/group.
extra option: -alloc-size=597

Allocated message queues 2, used 1
Using environment variable as configuration
Activating IO tunnel. Provider: [libgsiTunnel.so].
Added IO tunneling plugin libgsiTunnel.so for dcap-door.example.org:22128.
Using existing control connection to dcap-door.example.org:22128.
Setting hostname to dcap-door.example.org.
Got callback connection from dcap-door.example.org:35905 for session 2, myID 2.
cache_open -> OK
Enabling checksumming on write.
Cache open succeeded in 0.62s.
[7] Sending IOMCMD_WRITE.
Entered sendDataMessage.
get_reply: no special fields defined for that type of response.
get_reply: no special fields defined for that type of response.
Using system native close for [5].
[7] unplugging node
File checksum is: 460898156
Sending CLOSE for fd:7 ID:2.
Setting IO timeout to 300 seconds.
Entered sendDataMessage.
get_reply: no special fields defined for that type of response.
Server reply: ok destination [2].
Removing IO timeout handler.
Removing unneeded queue [2]
[7] destroing node
597 bytes in 0 seconds
Debugging

Using the dCache client interposition library.

Finding the GSI tunnel.

When the LD_PRELOAD library libpdcap.so variable produces errors finding the GSI tunnel it can be useful to specify the location of the GSI tunnel library directly using the following command:

```
[user] $ export DCACHE_IO_TUNNEL=/opt/d-cache/dcap/lib/libgsiTunnel.so
```

Please see [http://www.dcache.org/manuals/experts_docs/tunnel-HOWTO.html](http://www.dcache.org/manuals/experts_docs/tunnel-HOWTO.html) for further details on tunnel setup for the server.

dCap is a POSIX like interface for accessing dCache, allowing unmodified applications to access dCache transparently. This access method uses a proprietary data transfer protocol, which can emulate POSIX access across the LAN or WAN.
dCache Clients.

Unfortunately the client requires inbound connectivity and so it is not practical to use this protocol over the WAN as most sites will not allow inbound connectivity to worker nodes.

To make non dCache aware applications access files within dCache through dCap all that is needed is set the LD_PRELOAD environment variable to /opt/d-cache/dcap/lib/libpdcap.so.

```
[user] $ export LD_PRELOAD=/opt/d-cache/dcap/lib/libpdcap.so
```

Setting the LD_PRELOAD environment variable results in the library libpdcap.so overriding the operating system calls. After setting this environment variable, the standard shell command should work with dCap and GSIdCap URLs.

The following session demonstrates copying a file into dCache, checking the file is present with the ls command, reading the first 3 lines from dCache and finally deleting the file.

```
[user] $ cp /etc/group gsidcap://gsidcap-door.example.org:22128/pnfs/example.org/data/dteam/myFile
[user] $ ls gsidcap://gsidcap-door.example.org:22128/pnfs/example.org/data/dteam/DirOrFile
root:x:0:
demon:x:1:
bin:x:2:
[user] $ head -3 gsidcap://gsidcap-door.example.org:22128/pnfs/example.org/data/dteam/myFile
root:x:0:
demon:x:1:
bin:x:2:
[user] $ rm gsidcap://gsidcap-door.example.org:22128/pnfs/example.org/data/dteam/MyFile
```

**SRM**

dCache provides a series of clients one of which is the SRM client which supports a large number operations, but is just one Java application, the script name is sent to the Java applications command line to invoke each operation.

This page just shows the scripts command line and not the invocation of the Java application directly.

**Creating a new directory.**

Usage:

```
srmmkdir [[command line options]] [srmUrl]
```

Example:

The following example creates the directory /pnfs/example.org/data/dteam/myDir.

```
[user] $ srmmkdir srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/myDir
```

**Removing files from dCache**

Usage:

```
srmrm [[command line options]] [srmUrl ...]
```

```
[user] $ srmrm srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/myDir/myFile
```

**Removing empty directories from dCache**

It is allowed to remove only empty directories as well as trees of empty directories.
Usage:

`srmrmdir [command line options] [srmUrl]`

Examples:

```
[user] $ srmrmdir srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/myDir
```

```
[user] $ srmrmdir -recursive=true srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/myDir
```

### srmcp for SRM v1

Usage:

`srmcp [command line options] source...[destination]`

or

`srmcp [command line options] [-copyjobfile] file`

**Copying files to dCache**

```
[user] $ srmcp -webservice_protocol=http \ 
    file:///etc/group \ 
    srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/ 
    test_Srm.clinton.501.32050.20070907153055.0
```

**Copying files from dCache**

```
[user] $ srmcp -webservice_protocol=http \ 
    srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/ 
    test_Srm.clinton.501.32050.20070907153055.0 \ 
    file:///tmp/testfile1 -streams_num=1
```

### srmcp for SRM v2.2

**Getting the dCache Version**

The `srmping` command will tell you the version of dCache. This only works for authorized users and not just authenticated users.

```
[user] $ srmping -2 srm://srm-door.example.org:8443/pnfs
WARNING: SRM_PATH is defined, which might cause a wrong version of srm client to be executed
WARNING: SRM_PATH=/opt/d-cache/srm
VersionInfo : v2.2
backend_type:dCache
backend_version:production-1-9-1-11
```

### Space Tokens

Space token support must be set up and reserving space with the admin interface this is also documented in the SRM section and in the dCache wiki [http://trac.dcache.org/projects/dcache/wiki/manuals/SRM_2.2_Setup].
Space Token Listing

Usage:

get-space-tokens [command line options] [srmUrl]

Example 20.1. surveying the space tokens available in a directory.

```bash
[user] $ srm-get-space-tokens srm://srm-door.example.org:8443/pnfs/example.org/data/dteam -srm_protocol_version=2
```

A successful result:

```
return status code : SRM_SUCCESS
return status expl. : OK
Space Reservation Tokens:
148241
148311
148317
28839
148253
148227
148229
148289
148231
148352
```

Example 20.2. Listing the space tokens for a SRM:

```bash
[user] $ srm-get-space-tokens srm://srm-door.example.org:8443
Space Reservation Tokens:
145614
145615
144248
144249
25099
145585
145607
28839
145589
```

Space Reservation

Usage:

srm-reserve-space [[command line options]] [srmUrl]

```bash
[user] $ srm-reserve-space -desired_size 2000 -srm_protocol_version=2 -retention_policy=REPLICA -access_latency=ONLINE -guaranteed_size 1024 -lifetime 36000
```

A successful result:

```
Space token =144573
```
A typical failure

```bash
SRMClientV2 : srmStatusOfReserveSpaceRequest , contacting service http://srm-door.example.org:8443/srm/managerv2
status: code=SRM_NO_FREE_SPACE explanation= at Thu Nov 08 15:29:44 CET 2007 state Failed: no space available
lifetime = null
access latency = ONLINE
retention policy = REPLICA
guaranteed size = null
total size = 34
```

Also you can get info for this space token 144573:

```bash
[user] $ srm-get-space-metadata srm://srm-door.example.org:8443/pnfs/example.org/data/dteam -space_tokens=144573
Possible result:
```
```bash
Space Reservation with token=120047
    owner:VoGroup=/dteam VoRole=NULL
totalSize:1024
guaranteedSize:1024
unusedSize:1024
lifetimeAssigned:36000
lifetimeLeft:25071
accessLatency:ONLINE
retentionPolicy:REPLICA
```

Writing to a Space Token

Usage: srmcp [command line options] source(s) destination

Examples:

```bash
[user] $ srmcp -protocols=gsiftp -space_token=144573 \
file:///home/user/path/to/myFile \
srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/myFile
```
```bash
[user] $ srmcp -protocols=gsiftp -space_token=144573 \
file:///home/user/path/to/myFile1 \\
file:///home/user/path/to/myFile2 \
srm://srm-door.example.org:8443/pnfs/example.org/data/dteam
```

Space Metadata

Users can get the metadata available for the space, but the ability to query the metadata of a space reservation may be restricted so that only certain users can obtain this information.

```bash
[user] $ srm-get-space-metadata srm://srm-door.example.org:8443/pnfs/example.org/data/dteam -space_tokens=120049
WARNING: SRM_PATH is defined, which might cause a wrong version of srm client to be executed
WARNING: SRM_PATH=/opt/d-cache/srm
Space Reservation with token=120049
    owner:VoGroup=/dteam VoRole=NULL
totalSize:1024
guaranteedSize:1024
unusedSize:1024
lifetimeAssigned:36000
lifetimeLeft:30204
accessLatency:ONLINE
retentionPolicy:REPLICA
```
Space Token Release

Removes a space token from the SRM.

[user] $ srm-release-space srm://srm-door.example.org:8443 -space_token=15

Listing a file in SRM

SRM version 2.2 has a much richer set of file listing commands.

Usage:

srmls [command line options] srmUrl...

Example 20.3. Using srmls -l:

[user] $ srmls srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/testdir -2 0 /pnfs/example.org/data/dteam/testdir/
31 /pnfs/example.org/data/dteam/testdir/testFile1
31 /pnfs/example.org/data/dteam/testdir/testFile2
31 /pnfs/example.org/data/dteam/testdir/testFile3
31 /pnfs/example.org/data/dteam/testdir/testFile4
31 /pnfs/example.org/data/dteam/testdir/testFile5

Note

The -l option results in srmls providing additional information. Collecting this additional information may result in a dramatic increase in execution time.

Example 20.4. Using srmls -l:

[user] $ srmls -l srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/testdir -2 0 /pnfs/example.org/data/dteam/testdir/
storage type:PERMANENT
retention policy:CUSTODIAL
access latency:NEARLINE
locality:NEARLINE
locality: null
UserPermission: uid=18118 PermissionsRWX
GroupPermission: gid=2688 PermissionsRWX
WorldPermission: RX

- Status: null
- Type: FILE
If you have more than 1000 entries in your directory then dCache will return only the first 1000. To view directories with more than 1000 entries, please use the following parameters:

**srmls parameters**

- **-count=integer**    The number of entries to report.
- **-offset=integer**

**Example 20.5. Limited directory listing**

The first command shows the output without specifying `-count` or `-offset`. Since the directory contains less than 1000 entries, all entries are listed.

```bash
[user] $ srmls srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/dir1 \
    srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/dir2 \
0 /pnfs/example.org/data/dteam/dir1/
31 /pnfs/example.org/data/dteam/dir1/myFile1
28 /pnfs/example.org/data/dteam/dir1/myFile2
47 /pnfs/example.org/data/dteam/dir1/myFile3
0 /pnfs/example.org/data/dteam/dir2/
25 /pnfs/example.org/data/dteam/dir2/fileA
59 /pnfs/example.org/data/dteam/dir2/fileB
```

The following examples shows the result when using the `-count` option to listing the first three entries.

```bash
[user] $ srmls -count=3 srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/testdir  \
    -srm_protocol_version=2
0 /pnfs/example.org/data/dteam/testdir/
31 /pnfs/example.org/data/dteam/testdir/testFile1
31 /pnfs/example.org/data/dteam/testdir/testFile2
31 /pnfs/example.org/data/dteam/testdir/testFile3
```

In the next command, the `-offset` option is used to view a different set of entries.

```bash
[user] $ srmls -count=3 -offset=1 srm://srm-door.example.org:8443/pnfs/example.org/data/dteam/ \
    testdir -srm_protocol_version=2
0 /pnfs/example.org/data/dteam/testdir/
31 /pnfs/example.org/data/dteam/testdir/testFile1
31 /pnfs/example.org/data/dteam/testdir/testFile2
31 /pnfs/example.org/data/dteam/testdir/testFile3
31 /pnfs/example.org/data/dteam/testdir/testFile4
```

**ldap**

dCache is commonly deployed with the BDII. The information provider within dCache publishes information to BDII. To querying the dCache BDII is a matter of using the standard command ldapsearch. For grid the standard ldap port is set to 2170 from the previous value of 2135.

```bash
[user] $ ldapsearch -x -H ldap://localhost:2170 -b mds-vo-name=resource,o=grid > /tmp/ \
    ldap.output.ldif
[user] $ wc -l /tmp/ldap.output.ldif
205 /tmp/ldap.output.ldif
```

As can be seen from above even a single node standard install of dCache returns a considerable number of lines and for this reason we have not included the output, in this case 205 lines where written.
Using the LCG commands with dCache

The lcg_util RPM contains many small command line applications which interact with SRM implementations, these where developed independently from dCache and provided by the LCG grid computing effort.

Each command line application operates on a different method of the SRM interface. These applications where not designed for normal use but to provide components upon which operations can be built.

lcg-gt queries the BDII information server. This adds an additional requirement that the BDII information server can be found by lcg-gt, please only attempt to contact servers found on your user interface using.

```
[user$] $ lcg-infosites --vo dteam se
```

The lcg-gt Application

SRM provides a protocol negotiating interface, and returns a TURL (transfer URL). The protocol specified by the client will be returned by the server if the server supports the requested protocol.

To read a file from dCache using lcg-gt you must specify two parameters the SURL (storage URL), and the protocol (GSIdCap or GSI-FTP) you wish to use to access the file.

```
[user$] $ lcg-gt srm://srm-door.example.org/pnfs/example.org/data/dteam/group gsidcap
    gsidcap://gsidcap-door.example.org:22128/pnfs/example.org/data/dteam/group
-2147365977
-2147365976
```

Each of the above three lines contains different information. These are explained below.

gsidcap://gsidcap-door.example.org:22128/pnfs/example.org/data/dteam/group is the transfer URL (TURL).

-2147365977 is the SRM Request Id, Please note that it is a negative number in this example, which is allowed by the specification.

-2147365976 is the Unique identifier for the file with respect to the Request Id. Please note that with this example this is a negative number.

Remember to return your Request Id

dCache limits the number of Request Ids a user may have. All Request Ids should be returned to dCache using the command lcg-sd.

If you use lcg-gt to request a file with a protocol that is not supported by dCache the command will block for some time as dCache’s SRM interface times out after approximately 10 minutes.

The lcg-sd Application

This command should be used to return any TURLs given by dCache’s SRM interface. This is because dCache provides a limited number of TURLs available concurrently.

lcg-sd takes four parameters: the URL, the Request Id, the File Id with respect to the Request Id, and the direction of data transfer.
The following example is to complete the get operation, the values are taken form the above example of lcg-gt.

```
[user] $ lcg-sd srm://srm-door.example.org:22128/pnfs/example.org/data/dteam/group " -2147365977" " -2147365976" 0
```

### Negative numbers

dCache returns negative numbers for Request Id and File Id. Please note that lcg-sd requires that these values are places in double-quotes with a single space before the – sign.

The Request Id is one of the values returned by the lcg-gt command. In this example, the value (−2147365977) comes from the above example lcg-gt.

The File Id is also one of the values returned returned by the lcg-gt command. In this example, the value (−2147365976) comes from the above example lcg-gt.

The direction parameter indicates in which direction data was transferred: 0 for reading data and 1 for writing data.
Chapter 21. Pool Operations

Checksums

In dCache the storage of a checksum is part of a successful transfer.

- For an incoming transfer a checksum can be sent by the client (Client Checksum, it can be calculated during the transfer (Transfer Checksum) or it can be calculated on the server after the file has been written to disk (Server File Checksum).

- For a pool to pool transfer a Transfer Checksum or a Server File Checksum can be calculated.

- For data that is flushed to or restored from tape a checksum can be calculated before flushed to tape or after restored from tape, respectively.

Client Checksum

The client calculates the checksum before or while the data is sent to dCache. The checksum value, depending on when it has been calculated, may be sent together with the open request to the door and stored into Chimera before the data transfer begins or it may be sent with the close operation after the data has been transferred.

The dCap protocol provides both methods, but the dCap clients use the latter by default.

The FTP protocol does not provide a mechanism to send a checksum. Nevertheless, some FTP clients can (mis-)use the “site” command to send the checksum prior to the actual data transfer.

Transfer Checksum

While data is coming in, the server data mover may calculate the checksum on the fly.

Server File Checksum

After all the file data has been received by the dCache server and the file has been fully written to disk, the server may calculate the checksum, based on the disk file.

The default configuration is that a checksum is calculated on write, i.e. a Server File Checksum.

How to configure checksum calculation

Configure the calculation of checksums in the admin interface. The configuration has to be done for each pool separately.

```
(local) admin > cd poolname
(poolname) admin > csm set policy -option=on/off
(poolname) admin > save
```

The configuration will be saved in the file `path/to/pool/nameOfPooldirectory/setup`.

Use the command `csm info` to see the checksum policy of the pool.

```
(poolname) admin > csm info
Policies :
  on read : false
  on write : true
```
Pool Operations

The default configuration is to check checksums on write.

Use the command **help csm set policy** to see the configuration options.

The syntax of the command **csm set policy** is

```
csm set policy [-option=on [off]]
```

where **option** can be replaced by

**OPTIONS**

- **on transfer** If supported by the protocol, the checksum is calculated during file transfer.
- **on write** The checksum is calculated after the file has been written to disk.
- **on restore** The checksum is calculated after data has been restored from tape.
- **on flush** The checksum is calculated before data is flushed to tape.
- **getcrcfromhsm** If the HSM script supports it, the `pnfsid.crcval` file is read and stored in Chimera.
- **scrub** Pool data will periodically be verified against checksums. Use the command **help csm set policy** to see the configuration options.
- **enforcecrc** If no checksum has been calculated after or during the transfer, this option ensures that a checksum is calculated and stored in Chimera.

The option **onread** has not yet been implemented.

If an option is enabled a checksum is calculated as described. If there is already another checksum, the checksums are compared and if they match stored in Chimera.

**Important**

Do not change the default configuration for the option **enforcecrc**. This option should always be enabled as this ensures that there will always be a checksum stored with a file.

**Migration Module**

The purpose of the migration module is essentially to copy or move the content of a pool to one or more other pools.

Typical use cases for the migration module include:

- Vacating pools, that is, moving all files to other pools before decommissioning the pool.
- Caching data on other pools, thus distributing the load and increasing availability.
- As an alternative to the hopping manager.
Overview and Terminology

The migration module runs inside pools and hosts a number of migration jobs. Each job operates on a set of files on the pool on which it is executed and can copy or move those files to other pools. The migration module provides filters for defining the set of files on which a job operates.

The act of copying or moving a single file is called a migration task. A task selects a target pool and asks it to perform a pool to pool transfer from the source pool. The actual transfer is performed by the same component performing other pool to pool transfers. The migration module does not perform the transfer; it only orchestrates it.

The state of the target copy (the target state) as well as the source copy (the source state) can be explicitly defined. For instance, for vacating a pool the target state is set to be the same as the original source state, and the source state is changed to removed; for caching files, the target state is set to cached, and the source state is unmodified.

Sticky flags owned by the pin manager are never touched by a migration job, however the migration module can ask the pin manager to move the pin to the target pool. Care has been taken that unless the pin is moved by the pin manager, the source file is not deleted by a migration job, even if asked to do so. To illustrate this, assume a source file marked precious and with two sticky flags, one owned by foobar and the other by the pin manager. If a migration job is configured to delete the source file, but not to move the pin, the result will be that the file is marked cached, and the sticky flag owned by foobar is removed. The pin remains. Once it expires, the file is eligible for garbage collection.

All operations are idempotent. This means that a migration job can be safely rerun, and as long as everything else is unchanged, files will not be transferred again. Because jobs are idempotent they do not need to maintain persistent state, which in turns means the migration module becomes simpler and more robust. Should a pool crash during a migration job, the job can be rerun and the remaining files will be transferred.

Note

Please notice that a job is only idempotent as long as the set of target pools do not change. If pools go offline or are excluded as a result of a an exclude or include expression, then the idempotent nature of a job may be lost.

It is safe to run migration jobs while pools are in use. Once started, migration jobs run to completion and do only operate on those files that matched the selection filters at the time the migration job started. New files that arrive on the pool are not touched. Neither are files that change state after a migration job has been initialized, even though the selection filters would match the new state of the file. The exception to the rule is when files are deleted from the pool or change state so that they no longer match the selection filter. Such files will be excluded from the migration job, unless the file was already processed. Rerunning a migration job will force it to pick up any new files. Because the job is idempotent, any files copied before are not copied again.

Permanent migration jobs behave differently. Rather than running to completion, permanent jobs keep running until explicitly cancelled. They monitor the pool for any new files or state changes, and dynamically add or remove files from the transfer queue. Permanent jobs are made persistent when the save command is executed and will be recreated on pool restart. The main use case for permanent jobs is as an alternative to using a central hopping manager.

Idempotence is achieved by locating existing copies of a file on any of the target pools. If an existing copy is found, rather than creating a new copy, the state of the existing copy is updated to reflect the target state specified for the migration job. Care is taken to never make a file more volatile than it already
is: Sticky flags are added, or existing sticky flags are extended, but never removed or shortened; cached files may be marked precious, but not vice versa. One caveat is when the target pool containing the existing copy is offline. In that case the existence of the copy cannot be verified. Rather than creating a new copy, the task fails and the file is put back into the transfer queue. This behaviour can be modified by marking a migration job as eager. Eager jobs create new copies if an existing copy cannot be immediately verified. As a rule of thumb, permanent jobs should never be marked eager. This is to avoid that a large number of unnecessary copies are created when several pools are restarted simultaneously.

A migration task aborts whenever it runs into a problem. The file will be reinserted at the end of the transfer queue. Consequently, once a migration job terminates, all files have been successfully transferred. If for some reason tasks for particular files keep failing, then the migration job will never terminate by itself as it retries indefinitely.

Command Summary

Login to the admin interface and `cd` to a pool to use the `migration` commands. Use the command `help migration` to view the possibilities.

```
(llocal) admin > cd poolname
(poolname) admin > help migration
migration cancel [-force] JOB
migration clear
migration concurrency ID CONCURRENCY
migration copy [OPTIONS] TARGET...
migration info JOB
migration ls
migration move [OPTIONS] TARGET...
migration resume JOB
migration suspend JOB
```

The commands `migration copy`, `migration cache` and `migration move` create new migration jobs. These commands are used to copy files to other pools. Unless filter options are specified, all files on the source pool are copied. The syntax for these commands is the same; example `migration copy`:

```
migration copy [option] target
```

There are four different types of options. The filter options, transfer options, target options and lifetime options. Please run the command `help migration copy` for a detailed description of the various options.

The commands `migration copy`, `migration move` and `migration cache` take the same options and only differ in default values.

`migration move` The command `migration move` does the same as the command `migration copy` with the options:

- `-smode=delete` (default for `migration copy` is same).
- `-pins=move` (default for `migration copy` is keep).

Additionally it uses the option `-verify`.

`migration cache` The command `migration cache` does the same as the command `migration copy` with the option:

- `-tmode=cached`
Jobs are assigned a job ID and are executed in the background. The status of a job may be queried through the `migration info` command. A list of all jobs can be obtained through `migration ls`. Jobs stay in the list even after they have terminated. Terminated jobs can be cleared from the list through the `migration clear` command.

Jobs can be suspended, resumed and cancelled through the `migration suspend`, `migration resume` and `migration cancel` commands. Existing tasks are allowed to finish before a job is suspended or cancelled.

A migration job can be suspended and resumed with the commands `migration suspend` and `migration resume` respectively.

A migration job can be cancelled with the command `migration cancel`.

And terminated jobs can be cleared with the command `migration clear`.

---

```
(local) admin > cd poolname
(poolname) admin > migration copy -pnfsid=000060D40698B4BF4BE284666ED29CC826C7 pool2

(poolname) admin > migration ls
[1] FINISHED     migration copy -pnfsid=000060D40698B4BF4BE284666ED29CC826C7 pool2
[2] FINISHED     migration copy -pnfsid=00007C75C2E635CD472C8A75F5A90E4960D3 pool2
[5] FINISHED     migration move -pnfsid=000028C0C288190C47E7822B3DB2CA639582 pool2
[4] FINISHED     migration move -pnfsid=00007C75C2E635CD472C8A75F5A90E4960D3 pool2
(poolname) admin > migration clear
(poolname) admin > migration ls
[1] FINISHED     migration copy -pnfsid=000060D40698B4BF4BE284666ED29CC826C7 pool2
[2] FINISHED     migration copy -pnfsid=00007C75C2E635CD472C8A75F5A90E4960D3 pool2
[5] FINISHED     migration move -pnfsid=000028C0C288190C47E7822B3DB2CA639582 pool2
[4] FINISHED     migration move -pnfsid=00007C75C2E635CD472C8A75F5A90E4960D3 pool2
```
Except for the number of concurrent tasks, transfer parameters of existing jobs cannot be changed. This is by design to ensure idempotency of jobs. The concurrency can be altered through the migration concurrency command.

```
(poolname) admin > migration concurrency 4 2
(poolname) admin > migration info
Command      : migration copy pool2
State        : FINISHED
Queued       : 0
Attempts     : 6
Targets      : pool2
Completed    : 6 files; 20976068 bytes
Total        : 20976068 bytes
Concurrency  : 2
Running tasks:
```

## Examples

### Vacating a pool

To vacate the pool `sourcePool`, we first mark the pool read-only to avoid that more files are added to the pool, and then move all files to the pool `targetPool`. It is not strictly necessary to mark the pool read-only, however if not done there is no guarantee that the pool is empty when the migration job terminates. The job can be rerun to move remaining files.

```
(sourcePool) admin > pool disable -rdonly
(sourcePool) admin > migration move targetPool
[1] RUNNING   migration move targetPool
(sourcePool) admin > migration info 1
Command      : migration move targetPool
State        : RUNNING
Queued       : 0
Attempts     : 1
Targets      : targetPool
Completed    : 0 files; 0 bytes; 0%
Total        : 830424 bytes
Concurrency  : 1
Running tasks:
[0] 0001000000000000000BFAE0: TASK.Copying -> [targetPool@local]
(sourcePool) admin > migration info 1
Command      : migration move targetPool
State        : FINISHED
Queued       : 0
Attempts     : 1
Targets      : targetPool
Completed    : 1 files; 830424 bytes
Total        : 830424 bytes
Concurrency  : 1
Running tasks:
(sourcePool) admin > rep ls
(sourcePool) admin >
```

### Caching recently accessed files

Say we want to cache all files belonging to the storage group `atlas:default` and accessed within the last month on a set of low-cost cache pools defined by the pool group `cache_pools`. We can achieve this through the following command.

```
(sourcePool) admin > migration cache -target=pgroup -accessed=0..2592000 -storage=atlas:default cache_pools
```
The files on the source pool will not be altered. Any file copied to one of the target pools will be marked cached.

## Renaming a Pool

A pool may be renamed with the following procedure, regardless of the type of files stored on it.

Disable file transfers from and to the pool with

```plaintext
(poolname) admin > pool disable -strict
```

Then make sure, no transfers are being processed anymore. All the following commands should give no output:

```plaintext
(poolname) admin > queue ls queue
(poolname) admin > mover ls
(poolname) admin > p2p ls
(poolname) admin > pp ls
(poolname) admin > st jobs ls
(poolname) admin > rh jobs ls
```

Now the files on the pools have to be unregistered on the namespace server with

```plaintext
(poolname) admin > pnfs unregister
```

**Note**

Do not get confused that the commands `pnfs unregister` and `pnfs register` contain `pnfs` in their names. They also apply to dCache instances with Chimera and are named like that for legacy reasons.

Even if the pool contains precious files, this is no problem, since we will register them again in a moment. The files might not be available for a short moment, though. Log out of the pool, and stop the domain running the pool:

```plaintext
[root] # dcache stop poolDomain
Stopping poolDomain (pid=6070) 0 1 2 3 done
[root] #
```

Adapt the name of the pool in the layout files of your dCache installation to include your new pool-name. For a general overview of layout-files see the section called “Defining domains and services”.

For example, to rename a pool from `swimmingPool` to `carPool`, change your layout file from

```plaintext
[poolDomain]
[poolDomain/pool]
name=swimmingPool
```
Warning

Be careful about renaming pools in the layout after users have already been writing to them. This can cause inconsistencies in other components of dCache, if they are relying on pool names to provide their functionality. An example of such a component is the Chimera cache info.

Start the domain running the pool:

```
[root] # dcache start poolDomain
Starting poolDomain done
[root] #
```

Register the files on the pool with

```
(poolname) admin > pnfs register
```

Pinning Files to a Pool

You may pin a file locally within the private pool repository:

```
(poolname) admin > rep set sticky pnfsid on|off
```

the sticky mode will stay with the file as long as the file is in the pool. If the file is removed from the pool and recreated afterwards this information gets lost.

You may use the same mechanism globally: in the command line interface (local mode) there is the command

```
(local) admin > set sticky pnfsid
```

This command does:

1. Flags the file as sticky in the name space database (Chimera). So from now the filename is globally set sticky.

2. Will go to all pools where it finds the file and will flag it sticky in the pools.

3. All new copies of the file will become sticky.
Chapter 22. PostgreSQL and dCache

Vladimir Podstavkov
Mathias de Riese
Martin Radicke

PostgreSQL is used for various things in a dCache system: The SRM, the pin manager, the space manager, the replica manager, the pnfs companion, the billing, and the pnfs server might make use of one or more databases in a single or several separate PostgreSQL servers.

The SRM, the pin manager, the space manager, the replica manager, and the pnfs companion will use the PostgreSQL database as configured at cell start-up in the corresponding batch files. The billing will only write the accounting information into a database if it is configured with the option -useSQL. The pnfs server will use a PostgreSQL server if the pnfs-posgresql version is used. It will use several databases in the PostgreSQL server.

Installing a PostgreSQL Server

The preferred way to set up a PostgreSQL server should be the installation of the version provided by your OS distribution; however, version 8.3 or later is required.

Install the PostgreSQL server, client and JDBC support with the tools of the operating system.

Initialize the database directory (usually /var/lib/pgsql/data/), start the database server, and make sure that it is started at system start-up. This may be done with

```
[root] # /etc/init.d/postgresql start
[root] # chkconfig postgresql on
```

If the start-up script does not perform the initialization automatically, it might have to be done with

```
[root] # initdb -D /var/lib/pgsql/data/
```

and the server is started manually with

```
[root] # postmaster -i -D /var/lib/pgsql/data/ >logfile 2>&1 &
```

Configuring Access to PostgreSQL

In the installation guide instructions are given for configuring one PostgreSQL server on the admin node for all the above described purposes with generous access rights. This is done to make the installation as easy as possible. The access rights are configured in the file database_directory_name/data/pg_hba.conf. According to the installation guide the end of the file should look like

```
... 
# TYPE  DATABASE    USER        IP-ADDRESS        IP-MASK           METHOD
local   all         all                                             trust
host    all         all         127.0.0.1/32                        trust
host    all         all         ::1/128                             trust
host    all         all         HostIP/32                           trust
```

This gives access to all databases in the PostgreSQL server to all users on the admin host.

The databases can be secured by restricting access with this file. E.g.

```
# TYPE  DATABASE    USER        IP-ADDRESS        METHOD
local   all         postgres                      ident sameuser
local   all         pnfsserver                    password
local   all         all                           md5
host    all         all         127.0.0.1/32      md5
host    all         all         ::1/128           md5
host    all         all
```

To make the server aware of this you need to reload the configuration file as the user postgres by:

```
[root] # su - postgres
[root:postgres] # pg_ctl reload
```

And the password for e.g. the user pnfsserver can be set with

```
[postgres] # psql template1 -c "ALTER USER pnfsserver WITH PASSWORD 'yourPassword'
```

The pnfs server is made aware of this password by changing the variable dbConnectString in the file /usr/etc/pnfsSetup:

```
... export dbConnectString="user=pnfsserver password=yourPassword"
```

User access should be prohibited to this file with

```
[root] # chmod go-rwx /usr/etc/pnfsSetup
```

### Performance of the PostgreSQL Server

On small systems it should never be a problem to use one single PostgreSQL server for all the functions listed above. In the standard installation, the ReplicaManager, the pnfs companion are not activated by default. The billing will only write to a file by default.

Whenever the PostgreSQL server is going to be used for another functionality, the impact on performance should be checked carefully. To improve the performance, the functionality should be installed on a separate host. Generally, a PostgreSQL server for a specific functionality should be on the same host as the dCache cell accessing that PostgreSQL server, and the PostgreSQL server containing the databases for the pnfs server should run on the same host as the pnfs server and the PnfsManager cell of the dCache system accessing it. Accordingly, the pnfs companion and the pnfs server itself will use the same PostgreSQL server.

It is especially useful to use a separate PostgreSQL server for the billing cell.

**Note**

The following is work-in-progress.

Create PostgreSQL user with the name you will be using to run pnfs server. Make sure it has CREATEDB privilege.

```
[user] $ psql -U postgres template1 -c "CREATE USER johndoe with CREATEDB"
```
PostgreSQL and dCache

```bash
[user] $ dropuser pnfsserver
[user] $ createuser --no-adduser --createdb --pwprompt pnfsserver
```

Chapter 23. Complex Network Configuration

This chapter contains solutions for several non-trivial network configurations. The first section discusses the interoperation of dCache with firewalls and does not require any background knowledge about dCache other than what is given in the installation guide (Chapter 2, Installing dCache) and the first steps tutorial (Chapter 3, Getting in Touch with dCache). The following sections will deal with more complex network topologies, e.g. private subnets. Even though not every case is covered, these cases might help solve other problems, as well. Intermediate knowledge about dCache is required. Since most tasks require changes in the start-up configuration, the background information on how to configure the cell start-up, given in Chapter 6, The Cell Package will be useful.

Firewall Configuration

The components of a dCache instance may be distributed over several hosts (nodes). Some of these components are accessed from outside and consequently the firewall needs to be aware of that. This section assumes that all nodes are behind a firewall and have full access to each other. More complex setups are described in the following sections. Depending on the access method, certain ports have to be opened to only some of the nodes. We will describe the behaviour of a standard installation using the default values. Since dCache is very flexible, most port numbers may be changed in the configuration. The location (node) of any dCache component might also be changed from this standard.

The dCap Protocol

The dCap protocol should be used for local, trusted access only, because it is not authenticated. The traditional method is to mount pnfs locally on the client and use paths to the files on this local mount to address files. For this, the client has to be able to mount the NFS export of the pnfs server. It is also possible to use the dCap protocol with a URL instead of a local path within a pnfs mount. The URL has the form

```
dcap://dCapDoorHostFQN:dCapDoorPort/fullPnfsPath
```

If the dCapDoorPort is not specified, 22125 is used to establish a TCP connection to dCapDoorHostFQN (see next paragraph). In this case no NFS mount is needed anymore. However, the access is unauthenticated and therefore access is only granted if the “other” part of the UNIX rights are set accordingly. In other words: The user is mapped to nobody for unauthenticated dCap access.

In both cases (pnfs mount and URL access) the dCap client (dCap library or dcep command) will connect to the dCap door (doorDomain) on the admin node with TCP port 22125 (can be changed in config/dCacheSetup with dCapPort). After the pool manager selected a pool to be used for the transfer (the section called “The Pool Selection Mechanism” describes how to configure that selection mechanism.) this pool will establish the data connection to the client on a TCP port which has been selected by the client. The port range to use may be specified on the client side (e.g. by the -p option of the dcep command.)

The GSIdCap Protocol

The GSIdCap protocol is the dCap protocol with a GSI authentication wrapper (tunnel). The mechanism is the same as described for the URL-stype dCap protocol in the previous section. The only differ-
ence is the default port number. For the GSIdCap door the default port number is 22128. It is specified in \texttt{config/dCacheSetup} with the parameter \texttt{dCapGsiPort}.

Another difference between the dCap door and GSIdCap doors is that the dCap door is started on the admin node and there can only be one in the standard configuration, while there may be several GSIdCap doors on separate nodes. Correspondingly, ports have to be opened in a firewall. Note that it should not be necessary to run as many GSIdCap doors as GridFTP doors (see below), because no data is transferred through the GSIdCap door.

**The GridFTP Protocol**

A GridFTP client connects to one of the GridFTP doors on TCP port 2811. The data connections are established independent of the direction of the data transfer. In “active” FTP mode the server connects to the client while in “passive” FTP mode the client connects to the server.

In “active” FTP mode the pool selected by the pool manager (see the section called “The Pool Selection Mechanism”) will open one or more data connections to the client on a TCP port in the range between 20000 and 25000. In “passive” FTP mode, the client will establish the data connections to the GridFTP door in the same port range. The pool will connect to the door and the door will route the data traffic. It is not possible to establish a direct connection between pool and client in “passive” mode, because the FTP protocol redirection mechanism has to be triggered before the client sends the name of the requested file.

**The SRM Protocol**

An SRM is a webservice which uses the https as transport protocol and negotiates data transfers between the client and the server as well as between the server and another server. For the actual data transfer one of the other protocols is negotiated. Usually this is GridFTP - especially for wide-area transfers. There are two things to note about SRM-initiated GridFTP transfers:

For reading data, only “active” FTP mode will be used, i.e. the pool containing the data will connect to the client or to the server which should receive the data. For writing, only “passive” FTP mode will be used, i.e. the client or the pool containing the data will connect to the client or to the server which should receive the data.

Apart from SRM put and get operations which always copy data between one SRM and the client there is also a true SRM copy from one SRM to another SRM. There are two modes for SRM copy: “pull” and “push” mode. If the destination SRM is dCache based and SRM pull mode (default) is used, the destination pool will play the role of the GridFTP client, will contact the GridFTP door of the source instance and receive the data directly from the source pool (if the source system is a dCache system). If push mode is used and the source is a dCache based SRM, the source pool will be the GridFTP client and will send the data to the GridFTP door of the destination. All this might have to be considered when designing the system and configuring the firewall.

**Pool Selection**

Restricting wide-area transfers to a subset of your dCache pools may be done with the \textit{pool selection unit} in the pool manager. the section called “The Pool Selection Mechanism” contains a description on how to do that. This can be useful to ease firewall configurations, optimize throughput, and improve security.

**Protocol Overview**

The following table gives an overview about the default ports used by the client protocols supported by dCache. Note that all of them may be changed in \texttt{config/dCacheSetup}. 

---

**GridFTP Connections via two or more Network Interfaces**

**Description**

The host on which the GridFTP door is running has several network interfaces and is supposed to accept client connections via all those interfaces. The interfaces might even belong to separate networks with no routing from one network to the other.

As long as the data connection is opened by the GridFTP server (active FTP mode), there is no problem with having more than one interface. However, when the client opens the data connection (passive FTP mode), the door (FTP server) has to supply it with the correct interface it should connect to. If this is the wrong interface, the client might not be able to connect to it, because there is no route or the connection might be inefficient.

Also, since a GridFTP server has to authenticate with an SSL grid certificate and key, there needs to be a separate certificate and key pair for each name of the host. Since each network interface might have a different name, several certificates and keys are needed and the correct one has to be used, when authenticating via each of the interfaces.

**Solution**

Start a separate GridFTP server cell on the host for each interface on which connections should be accepted.

The cells may be started in one domain or in separate domains. The cells have to have different names, since they are well known cells. Each cell has to be configured, only to listen on the interface it should serve with the `listen` option. The locations of the grid host certificate and key files for the interface have to be specified explicitly with the `service-cert` and `service-key` options.

The following example shows a setup for two network interfaces with the hostnames `door-a.grid.domain` (111.111.111.5) and `door-b.other.domain` (222.222.222.5) which are served by two GridFTP door cells in one domain:
Example 23.1. Batch file for two GridFTP doors serving separate network interfaces

```bash
set printout default 2
set printout CellGlue none
onerror shutdown
check -strong setupFile
copy file:${setupFile} context:setupContext
import context -c setupContext
check -strong sshPort ftpPort
create dmg.cells.services.RoutingManager RoutingMngr
create dmg.cells.services.LocationManager lm 
  "${serviceLocatorHost} ${serviceLocatorPort}"
create dmg.cells.services.login.LoginManager GFTP-door-a 
  "2811 "
  -listen=111.111.111.5 
  -export 
  diskCacheV111.doors.GsiFtpDoorV1 
  -prot=raw 
  -service-cert=/etc/grid-security/door-a.grid.domain-cert.pem 
  -service-key=/etc/grid-security/door-a.grid.domain-key.pem 
  .. ..
create dmg.cells.services.login.LoginManager GFTP-door-b 
  "2811 "
  -listen=222.222.222.5 
  -export 
  diskCacheV111.doors.GsiFtpDoorV1 
  -prot=raw 
  -service-cert=/etc/grid-security/door-b.other.domain-cert.pem 
  -service-key=/etc/grid-security/door-b.other.domain-key.pem 
  .. ..
```

This batch file is very similar to the batch file for the GridFTP door in the standard setup. (Comments have been left out.) It only contains an additional create command for the second cell and the emphasized changes within the two create commands: The cell names, the -listen option with the IP address of the corresponding interface and the -service-cert and -service-key options with the host certificate and key files.

GridFTP with Pools in a Private Subnet

Description

If pool nodes of a dCache instance are connected to a secondary interface of the GridFTP door, e.g., because they are in a private subnet, the GridFTP door will still tell the pool to connect to its primary interface, which might be unreachable.

The reason for this is that the control communication between the door and the pool is done via the network of TCP connections which have been established at start-up. In the standard setup this communication is routed via the dCache domain. However, for the data transfer, the pool connects to the GridFTP door. The IP address it connects to is sent by the GridFTP door to the pool via the control connection. Since the GridFTP door cannot find out which of its interfaces the pool should use, it normally sends the IP address of the primary interface.
Solution

Tell the GridFTP door explicitly which IP it should send to the pool for the data connection with the `-ftp-adapter-internal-interface` option. E.g. if the pools should connect to the secondary interface of the GridFTP door host which has the IP address 10.0.1.1, the following batch file would be appropriate:

Example 23.2. Batch file for two GridFTP doors serving separate network interfaces

```plaintext
set printout default 2
set printout CellGlue none
onerror shutdown
check -strong setupFile
copy file:${setupFile} context:setupContext
import context -c setupContext
check -strong serviceLocatorPort serviceLocatorHost
check -strong sshPort ftpPort
create dmg.cells.services.RoutingManager RoutingMgr
create dmg.cells.services.LocationManager lm "${serviceLocatorHost} ${serviceLocatorPort}"
create dmg.cells.services.login.LoginManager GFTP "2811 -export diskCacheV111.doors.GsiFtpDoorV1 -prot=raw -clientDataPortRange=${clientDataPortRange} -root=${ftpBase} -kpwd-file=${kpwdFile} -tlog=/tmp/dcache-ftp-tlog -maxLogin=100 -brokerUpdateTime=5 -protocolFamily=gsiftp -loginBroker=LoginBroker -poolManagerTimeout=5400 -pnfsTimeout=120 -maxRetries=80 -maxStreamsPerClient=10 -ftp-adapter-internal-interface=10.0.1.1"
```

This batch file is very similar to the batch file for the GridFTP door in the standard setup. (Comments have been left out.) The emphasized last line has the desired effect.

Doors in the DMZ

Description

Some doors - e.g. for grid access - are located in the DMZ while the rest of the dCache instance is in the intranet. The firewall is configured in such a way that the doors cannot reach the location manager (usually on the admin node together with the pool manager) via port 11111 (or as configured in the variable serviceLocatorPort in config/lmSetup).

Solution

Please contact <support@dcache.org> if you need a solution for this problem.
Chapter 24. Accounting

The raw information about all dCache activities can be found in /var/lib/dcache/billing/YYYY/MM/billing-YYYY.MM.DD. A typical line looks like

05.31 22:35:16 [pool:pool-name:transfer] [000100000000000000001320,24675] myStore:STRING@osm 24675 474 true {GFtp-1.0 client-host-fqn 37592} {0:**}

The first bracket contains the pool name, the second the pnfs ID and the size of the file which is transferred. Then follows the storage class, the actual amount of bytes transferred, and the number of milliseconds the transfer took. The next entry is true if the transfer was a wrote data to the pool. The first braces contain the protocol, client FQN, and the client host data transfer listen port. The final bracket contains the return status and a possible error message.

The dCache web interface (described in the section called “The Web Interface for Monitoring dCache”) contains under the menu point “Actions Log” summary information extracted from the information in the billing-directory.

The accounting information can also be redirected into a database. When interested in this feature, please contact <support@dcache.org>.
Chapter 25. Protocols

dCap options mover and client options

Patrick Fuhrmann
Tigran Mkrtchyan

dCap is the native random access I/O protocol for files within dCache. In addition to the usual data transfer mechanisms, it supports all necessary file metadata and name space manipulation operations.

In order to optimize I/O transferrates and memory consumption dCap allows to configure parameters within the client and the server. e.g:

- TCP Socket send and receive buffer sizes.
- I/O buffers sizes.

TCP send/recv buffer sizes from the servers point of view

There are two parameters per I/O direction, determining the actual TCP send/recv buffer size used for each transfer. Those values can be set within the config/pool.batch file on the pool nodes.

- defaultSend/RecvBufferSize : this value is used if the dCap client doesn’t try to set this value. The default value for this parameter is 256K Bytes.
- maxSend/RecvBufferSize : this value is the maximum value, the mover is allowed to use. It’s used if either the defaultSend/RecvBufferSize is larger or the client asks for a larger value. The default value for this parameter is 1MBytes.

On the server side, the max/defaultSend/RecvBufferSize value can either be set in the config/pool.batch file or in the config/*.poollist files.

Using the batch context:

```
set context dCap3-maxSendBufferSize value in bytes
set context dCap3-maxRecvBufferSize value in bytes
set context dCap3-defaultSendBufferSize value in bytes
set context dCap3-defaultRecvBufferSize value in bytes
```

Or it may specified in the create ... command line

```
create diskCacheV11.pools.MultiProtocolPool2 ${0} 
  *!MoverMap 
  ${1} 
  -defaultSendBufferSize=value in bytes 
  *** 
  -${2} -${3} -${4} -${5} -${6} -${7} -${8} 
```

The most appropriate way to specify those values on the server side is certainly to add the corresponding entry in the config/...poollist. The entry would look like
TCP send/recv buffer sizes from the dCap clients point of view

For a full list of dCap library API calls and dccp options, please refer to to http://www.dcache.org/manuals/libdcap.shtml and http://www.dcache.org/manuals/dccp.shtml respectively. To set the local and remote TCP buffer send and receive buffers either use the API call dc_setTCP Send/Receive Buffer(int size) or the \( -r \) SIZE -s SIZE dccp options. In both cases the value is transferred to the remote mover which tries to set the corresponding values. Please note not the server protects itself by having a maximum size for those values which it doesn’t exceed. Please check the section ‘TCP send/recv buffer sizes from the servers point of view’ to learn how to change those values.

Specifying dCap open timeouts

Patrick Fuhrmann

In cases where dccp/dcap requests a file which is still on tertiary storage, the user resp. the administrator might what to limit the time, dccp/dCap waits in the open call until the file has been fetched from backend storage. This, so called openTimeout, can be specified on the server or on the client. In all cases the \(-\text{keepAlive}\) must be specified with an appropriate number of seconds on the cell create command in the door batch files. The following mechanisms are available to specify open timeouts:

<table>
<thead>
<tr>
<th>Precedence</th>
<th>Mechanism</th>
<th>Key Name</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lowest</td>
<td>context</td>
<td>dCap-openTimeout</td>
<td>set context dCap-openTimeout 200</td>
</tr>
<tr>
<td></td>
<td>context</td>
<td>openTimeout</td>
<td>set context openTimeout 200</td>
</tr>
<tr>
<td></td>
<td>cell create</td>
<td>openTimeout</td>
<td>-openTimeout=200</td>
</tr>
<tr>
<td>Highest</td>
<td>dccp command line</td>
<td>-o</td>
<td>dccp -o200 SOURCE DESTINATION</td>
</tr>
</tbody>
</table>

# dCap Door (create command line example)

```sh
create dmg.cells.services.login.LoginManager DCap-2 
  "${specialDCapPort} 
  diskCacheV11 doors.DCapDoor 
  -export 
  -keepAlive=60 
  -openTimeout=300 
  -loginBroker=LoginBroker"
```

# dCap Door (context example)
If the openTimeout expires while a read transfer is already active, this transfer will be interrupted, but it will automatically resume because the client can’t distinguish between a network failure and a timeout. So the timeout disturbs the read but it will finally succeed. This is different for write. If a write is interrupted by a timeout in the middle of a transfer, dccp will stuck. (This is not a feature and needs further investigation).

### Using the dCap protocol for strict file checking

Patrick Fuhrmann
Tigran Mkrtchyan

The dCap protocol allows to check whether a dataset is on tape only or has a copy on a dCache disk. The dCap library API call is `int dc_check(const char *path, const char *location)` and the dccp options are `-t -1 -P`. For a full list of dCap library API calls and dccp options, please refer to to [http://www.dcache.org/manuals/libdcap.shtml](http://www.dcache.org/manuals/libdcap.shtml) and [http://www.dcache.org/manuals/dccp.shtml](http://www.dcache.org/manuals/dccp.shtml) respectively. Using a standard dCache installation those calls will return a guess on the file location only. It is neither checked whether the file is really on that pool or if the pool is up. To get a strict checking a dCap door has to be started with a special `(-check=strict)` option.

```
# dCap Door
#
create dmg.cells.services.login>LoginManager DCap-strict "${specialDCapPort}"
diskCacheV111.doors.DCapDoor -export -check=strict -prot=telnet -localOk -maxLogin=1500 -brokerUpdateTime=120 -protocolFamily=dcap -loginBroker=LoginBroker"
```

This door will do a precise checking `(-check=strict)`. To get the dCap lib and dccp to use this door only, the DCACHE_DOOR environment variable has to be set to `doorHost:specialDCapPort` in the shell, dccp is going to be used. In the following example we assume that the specialDCapPort has been set to `23126`:

```
[user] $ export DCACHE_DOOR=dcachedoorhost:23126
[user] $ dcp -P -t -l /pnfs/domain.tv/data/cms/users/waste.txt
```

197
If `dccp` returns `File is not cached` and this dCache instance is connected to an HSM, the file is no longer on one of the dCache pools but is assumed to have a copy within the HSM. If the `dccp` returns this message and no HSM is attached, the file is either on a pool which is currently down or the file is lost.

**Passive dCap**

Tigran Mkrtchyan  
Patrick Fuhrmann

The dCap protocol, similar to FTP, uses a control channel to request a transfer which is subsequently done through data channels. Per default, the data channel is initiated by the server, connecting to an open port in the client library. This is commonly known as active transfer. Starting with dCache 1.7.0 the dCap protocol supports passive transfer mode as well, which consequently means that the client connects to the server pool to initiate the data channel. This is essential to support dCap clients running behind firewalls and within private networks.

**Preparing the server for dCap passive transfer**

The port(s), the server pools should listen on, can be specified by the `org.dcache.net.tcp.portrange` variable, as part of the 'java_options' directive in the `config/dCacheSetup` configuration file. A range has to be given if pools are split among multiple JVMs. E.g:

```java
java_options="-server ... -Dorg.dcache.dcap.port=0 -Dorg.dcache.net.tcp.portrange=33115:33145"
```

**Switching the dCap library resp. dccp to PASSIVE**

**Note**

The commonly used expression 'passive' is seen from the server perspective and actually means 'server passive'. From the client perspective this is of course 'active'. Both means that the client connects to the server to establish the data connection. This mode is supported by the server starting with 1.7.0 and dccp with 1-2-40 (included in 1.7.0)

The following dCap API call switches all subsequent dc_open calls to server-passive mode if this mode is supported by the corresponding door. (dCache Version $\geq$ 1.7.0).

```java
void dc_setClientActive()
```

The environment variable `DCACHE_CLIENT_ACTIVE` switches the dCap library to server-passive. This is true for dCap, dCap preload and `dccp`.

`dccp` switches to server-passive when issuing the `-A` command line option.

**Access to SRM and GridFTP server from behind a firewall**

Timur Perelmutov  
Mathias de Riese
This describes firewall issues from the clients perspective. The section called “Firewall Configuration” discusses the server side.

When files are transferred in GridFTP active mode from GridFTP server to the GridFTP client, server establishes data channel(s) by connecting to the client. In this case client creates a TCP socket, bound to some particular address on the client host, and sends the client host IP and port to the server. If the client host is running a firewall, firewall might refuse server’s connection to the client’s listening socket. Common solution to this problem is establishing a range of ports on the client’s host that are allowed to be connected from Internet by changing firewall rules. Once the port range is defined the client can be directed to use one of the ports from the port ranges when creating listening TCP sockets.

**Access with srmcp**

If you are using srmcp as a client you need to do the following:

- create a directory $HOME/.globus if it does not exist.
- create and/or edit a file $HOME/.globus/cog.properties by appending a new line reading:

```
tcp.port.range=min,max
```

where min and max are the lower and upper bounds of the port range.

With the latest srmcp release you can use the globus_tcp_port_range option:

```
[user] $ srmcp -globus_tcp_port_range=minValue:maxValue ...
```

A range of ports open for TCP connections is specified as a pair of positive integers separated by "::". This is not set by default.

**Access with globus-url-copy**

If you are transferring files from gridftp server using globus-url-copy, you need to define an environment variable GLOBUS_TCP_PORT_RANGE, in the same shell in which globus-url-copy will be executed.

In sh/bash you do that by invoking the following command:

```
[user] $ export GLOBUS_TCP_PORT_RANGE="min,max"
```

in csh/tcsh you invoke:

```
[user] $ setenv GLOBUS_TCP_PORT_RANGE "min,max"
```

here min and max are again the lower and upper bounds of the port range.

**Disableing unauthenticated dCap via SRM**

In some cases SRM transfers fail because they are tried via the plain dCap protocol (URL starts with dcap://). Since plain dCap is unauthenticated, the dCache server will have no information about the user trying to access the system. While the transfer will succeed if the UNIX file permissions allow access to anybody (e.g. mode 777), it will fail otherwise.
Usually all doors are registered in SRM as potential access points for dCache. During a protocol negotiation the SRM chooses one of the available doors. You can force `srmcp` to use the GSIdCap protocol (`-protocol=gsidcap`) or you can unregister plain, unauthenticated dCap from known protocols: From the file `config/door.batch` remove `-loginBroker=LoginBroker` and restart dCap door with

```
[root] # jobs/door stop
[root] # jobs/door -logfile=dCacheLocation/log/door.log start
```
Chapter 26. Advanced Tuning

The use cases described in this chapter are only relevant for large-scale dCache instances which require special tuning according to a longer experience with client behaviour.

Multiple Queues for Movers in each Pool

Description

Client requests to a dCache system may have rather diverse behaviour. Sometimes it is possible to classify them into several typical usage patterns. An example are the following two concurrent usage patterns:

Data is copied with a high transfer rate to the dCache system from an external source. This is done via the GridFTP protocol. At the same time batch jobs on a local farm process data. Since they only need a small part of each file, they use the dCap protocol via the dCap library and seek to the position in the file they are interested in, read a few bytes, do a few hours of calculations, and finally read some more data.

As long as the number of active requests does not exceed the maximum number of allowed active requests, the two types of requests are processed concurrently. The GridFTP transfers complete at a high rate while the processing jobs take hours to finish. This maximum number of allowed requests is set with mover set max active and should be tuned according to capabilities of the pool host.

However, if requests are queued, the slow processing jobs might clog up the queue and not let the fast GridFTP request through, even though the pool just sits there waiting for the processing jobs to request more data. While this could be temporarily remedied by setting the maximum active requests to a higher value, then in turn GridFTP request would put a very high load on the pool host.

The above example is pretty realistic: As a rule of thumb, GridFTP requests are fastest, dCap requests with the dccp program are a little slower and dCap requests with the dCap library are very slow. However, the usage patterns might be different at other sites and also might change over time.

Solution

Use separate queues for the movers, depending on the door initiating them. This easily allows for a separation of requests of separate protocols. (Transfers from and to a tape backend and pool-to-pool transfers are handled by separate queues, one for each of these transfers.)

A finer grained queue selection mechanism based on, e.g. the IP address of the client or the file which has been requested, is not possible with this mechanism. However, the pool selection unit (PSU) may provide a separation onto separate pools using those criteria.

In the above example, two separate queues for fast GridFTP transfers and slow dCap library access would solve the problem. The maximum number of active movers for the GridFTP queue should be set to a lower value compared to the dCap queue since the fast GridFTP transfers will put a high load on the system while the dCap requests will be mostly idle.

Configuration

For a multi mover queue setup, the pools have to be told to start several queues and the doors have to be configured to use one of these. It makes sense to create the same queues on all pools. This is done by the following change to the file /etc/dcache/dcache.conf:
Each door may be configured to use a particular mover queue. The pool, selected for this request, does not depend on the selected mover queue. So a request may go to a pool which does not have the particular mover queue configured and will consequently end up in the default mover queue of that pool.

All requests send from this kind of door will ask to be scheduled to the given mover queue. The selection of the pool is not affected.

The doors are configured to use a particular mover queue as in the following example:

Create the queues queueA and queueB, where queueA shall be the queue for the GridFTP transfers and queueB for dCap.

If the pools should not all have the same queues you can define queues for pools in the layout file. Here you might as well define that a specific door is using a specific queue.

In this example queueC is defined for pool1 and queueD is defined for pool2. The GridFTP door running in the domain myDoors is using the queue queueB.

There is always a default queue called regular. Transfers not requesting a particular mover queue or requesting a mover queue not existing on the selected pool, are handled by the regular queue.

The pool cell commands mover ls and mover set max active have a -queue option to select the mover queue to operate on. Without this option, mover set max active will act on the default queue while mover ls will list all active and waiting client transfer requests.

For the dCap protocol, it is possible to allow the client to choose another queue name than the one defined in the file dcache.conf. To achieve this the property dcapIoQueueOverwrite needs to be set to allowed.

Create the queues queueA and queue_dccp, where queueA shall be the queue for dCap.

With the dccp command the queue can now be specified as follows:
Since *dccp* requests may be quite different from other requests with the dCap protocol, this feature may be used to use separate queues for *dccp* requests and other dCap library requests. Therefore, the *dccp* command may be changed in future releases to request a special *dccp*-queue by default.

Chapter 27. dCache Clients

The SRM Client Suite

An SRM URL has the form srm://dmx.lbl.gov:6253//srm/DRM/srmv1?SFN=/tmp/try1 and the file URL looks like file:///tmp/aaa.

srmcp

srmcp — Copy a file from or to an SRM or between two SRMs.

Synopsis

srmcp [option...] sourceUrl destUrl

Arguments

sourceUrl The URL of the source file.
destUrl The URL of the destination file.

Options

gss_expected_name To enable the user to specify the gss expected name in the DN (Distinguished Name) of the srm server. The default value is host.

If the CN of host where srm server is running is CN=srm/tam01.fnal.gov, then gss_expected_name should be srm.

[user] $ srmcp --gss_expected_name=srm sourceUrl destinationUrl

globus_tcp_port_range To enable the user to specify a range of ports open for tcp connections as a pair of positive integers separated by “:”, not set by default.

This takes care of compute nodes that are behind firewall.

globus_tcp_port_range=40000:50000

[user] $ srmcp --globus_tcp_port_range=minVal:maxVal sourceUrl destinationUrl

streams_num To enable the user to specify the number of streams to be used for data transfer. If set to 1, then stream mode is used, otherwise extended block mode is used.

[user] $ srmcp --streams_num=1 sourceUrl destinationUrl

server_mode To enable the user to set the (gridftp) server mode for data transfer. Can be active or passive, passive by default.
This option will have effect only if transfer is performed in a stream mode (see streams_num)

[user] $ srmcp --streams_num=1 --
server_mode=active sourceUrl destinationUrl

Description

srmstage

srmstage — Request staging of a file.

Synopsis

srmstage [srmUrl...]

Arguments

srmUrl The URL of the file which should be staged.

Description

Provides an option to the user to stage files from HSM to dCache and not transfer them to the user right away. This case will be useful if files are not needed right away at user end, but its good to stage them to dcache for faster access later.

dccp

dccp

dccp — Copy a file from or to a dCache server.

Synopsis

dccp [option...] sourceUrl destUrl

Arguments

The following arguments are required:

sourceUrl The URL of the source file.

destUrl The URL of the destination file.

Description

The dccp utility provides a cp(1) like functionality on the dCache file system. The source must be a single file while the destination could be a directory name or a file name. If the directory is a destination,
a new file with the same name as the source name will be created there and the contents of the source will be copied. If the final destination file exists in dCache, it won’t be overwritten and an error code will be returned. Files in regular file systems will always be overwritten if the -i option is not specified. If the source and the final destination file are located on a regular file system, the deep utility can be used similar to the cp(1) program.

### Options

The following arguments are optional:

- `-a` Enable read-ahead functionality.
- `-b bufferSize` Set read-ahead buffer size. The default value is 1048570 Bytes. To disable the buffer this can be set to any value below the default. deep will attempt to allocate the buffer size so very large values should be used with care.
- `-B bufferSize` Set buffer size. The size of the buffer is requested in each request, larger buffers will be needed to saturate higher bandwidth connections. The optimum value is network dependent. Too large a value will lead to excessive memory usage, too small a value will lead to excessive network communication.
- `-d debug level` Set the debug level. `debug level` is a integer between 0 and 127. If the value is 0 then no output is generated, otherwise the value is formed by adding together one or more of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Enabled output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Error messages</td>
</tr>
<tr>
<td>2</td>
<td>Info messages</td>
</tr>
<tr>
<td>4</td>
<td>Timing information</td>
</tr>
<tr>
<td>8</td>
<td>Trace information</td>
</tr>
<tr>
<td>16</td>
<td>Show stack-trace</td>
</tr>
<tr>
<td>32</td>
<td>IO operations</td>
</tr>
<tr>
<td>64</td>
<td>Thread information</td>
</tr>
</tbody>
</table>
- `-h replyHostName` Bind the callback connection to the specific hostname interface.
- `-i` Secure mode. Do not overwrite the existing files.
- `-l location` Set location for pre-stage. If the location is not specified, the local host of the door will be used. This option must be used with the -P option.
- `-p first_port:last_port` Bind the callback data connection to the specified TCP port/range set port range. Delimited by the ‘:’ character, the first_port is required but the last_port is optional.
- `-P` Pre-stage. Do not copy the file to a local host but make sure the file is on disk on the dCache server.
- `-r bufferSize` TCP receive buffer size. The default is 256K. Setting to 0 uses the system default value. Memory usage will increase with higher values, but performance better.
-s bufferSize

TCP send buffer size. The default is 256K. Setting to 0 uses the system default value.

-t time

Stage timeout in seconds. This option must be used with the -P option.

Examples:

To copy a file to dCache:

[user] $ dccp /etc/group dcap://example.org/pnfs/desy.de/gading/

To copy a file from dCache:

[user] $ dccp dcap://example.org/pnfs/desy.de/gading/group /tmp/

Pre-Stage request:

[user] $ dccp -P -t 3600 -l example.org /acs/user_space/data_file

stdin:

[user] $ tar cf - data_dir | dccp - /acs/user_space/data_arch.tar

stdout:

[user] $ dccp /acs/user_space/data_arch.tar - | tar xf -

Chapter 28. dCache Cell Commands

This is the reference to all (important) cell commands in dCache. You should not use any command not documented here, unless you really know what you are doing. Commands not in this reference are used for debugging by the developers.

This chapter serves two purposes: The other parts of this book refer to it, whenever a command is mentioned. Secondly, an administrator may check here, if he wonders what a command does.

Common Cell Commands

pin

pin — Adds a comment to the pinboard.

Synopsis

code

pin comment

Arguments

code

comment A string which is added to the pinboard.

Description

info

info — Print info about the cell.

Synopsis

code

info [-a] [-l]

Arguments

-a Display more information.
-l Display long information.

Description

The info printed by info depends on the cell class.

dump pinboard

dump pinboard — Dump the full pinboard of the cell to a file.
dCache Cell Commands

Synopsis

dump pinboard filename

Arguments

filename The file the current content of the pinboard is stored in.

Description

show pinboard

show pinboard — Print a part of the pinboard of the cell to STDOUT.

Synopsis

show pinboard [lines]

Arguments

lines The number of lines which are displayed. Default: all.

Description

PnfsManager Commands

pnfsidof

pnfsidof — Print the pnfs id of a file given by its global path.

Synopsis

pnfsidof globalPath

Description

Print the pnfs id of a file given by its global path. The global path always starts with the “VirtualGlobalPath” as given by the “info”-command.

flags remove

flags remove — Remove a flag from a file.

Synopsis
flags remove pnfsId key ...

Arguments

pnfsId The pnfs id of the file of which a flag will be removed.
key flags which will be removed.

Description

flags ls

flags ls — List the flags of a file.

Synopsis

flags ls pnfsId

pnfsId The pnfs id of the file of which a flag will be listed.

Description

flags set

flags set — Set a flag for a file.

Synopsis

flags set pnfsId key=value ...

Arguments

pnfsId The pnfs id of the file of which flags will be set.
key The flag which will be set.
value The value to which the flag will be set.

Description

metadataof

metadataof — Print the meta-data of a file.

Synopsis

metadataof [ pnfsId ] [ globalPath ] [-v] [-n] [-se]
Arguments

pnfsId       The pnfs id of the file.
globalPath   The global path of the file.

Description

pathfinder

pathfinder — Print the global or local path of a file from its PNFS id.

Synopsis

pathfinder pnfsId [-global] [-local]

Arguments

pnfsId       The pnfs Id of the file.
            -global  Print the global path of the file.
            -local   Print the local path of the file.

Description

set meta

set meta — Set the meta-data of a file.

Synopsis

set meta [pnfsId] [globalPath] uid gid perm levelInfo...

Arguments

pnfsId       The pnfs id of the file.
globalPath   The global path of the file.
uid          The user id of the new owner of the file.
gid          The new group id of the file.
perm         The new file permissions.
levelInfo    The new level information of the file.

Description
**storageinfoof**

storageinfoof — Print the storage info of a file.

**Synopsis**

storageinfoof [pnfsId] | [globalPath] [-v] [-n] [-se]

**Arguments**

pnfsId The pnfs id of the file.
globalPath The global path of the file.

**Description**

**cacheinfoof**

cacheinfoof — Print the cache info of a file.

**Synopsis**

cacheinfoof [pnfsId] | [globalPath]

**Arguments**

pnfsId The pnfs id of the file.
globalPath The global path of the file.

**Description**

**Pool Commands**

**rep ls**

rep ls — List the files currently in the repository of the pool.

**Synopsis**

rep ls [pnfsId...] | [-l= s | p | l | u | nc | e ... ] [-s= k | m | g | t ]

pnfsId The pnfs ID(s) for which the files in the repository will be listed.

-l List only the files with one of the following properties:

| s | sticky files |
| p | precious files |
| l | locked files |
dCache Cell Commands

<table>
<thead>
<tr>
<th>u</th>
<th>files in use</th>
</tr>
</thead>
<tbody>
<tr>
<td>nc</td>
<td>files which are not cached</td>
</tr>
<tr>
<td>e</td>
<td>files with an error condition</td>
</tr>
</tbody>
</table>

-s
Unit, the filesize is shown:

<table>
<thead>
<tr>
<th>k</th>
<th>data amount in KBytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>m</td>
<td>data amount in MBytes</td>
</tr>
<tr>
<td>g</td>
<td>data amount in GBytes</td>
</tr>
<tr>
<td>t</td>
<td>data amount in TBytes</td>
</tr>
</tbody>
</table>

**Description**

**st set max active**

**st set max active** — Set the maximum number of active store transfers.

**Synopsis**

```
st set max active maxActiveStoreTransfers
```

```
maxActiveStoreTransfers The maximum number of active store transfers.
```

**Description**

Any further requests will be queued. This value will also be used by the cost module for calculating the performance cost.

**rh set max active**

**rh set max active** — Set the maximum number of active restore transfers.

**Synopsis**

```
rh set max active maxActiveRetoreTransfers
```

```
maxActiveRetoreTransfers The maximum number of active restore transfers.
```

**Description**

Any further requests will be queued. This value will also be used by the cost module for calculating the performance cost.

**mover set max active**

**mover set max active** — Set the maximum number of active client transfers.

**Synopsis**

```
mover set max active maxActiveClientTransfers [-queue=moverQueueName]
```

215
maxActiveClientTransfers The maximum number of active client transfers.

moverQueueName The mover queue for which the maximum number of active transfers should be set. If this is not specified, the default queue is assumed, in order to be compatible with previous versions which did not support multiple mover queues (before version 1.6.6).

**Description**

Any further requests will be queued. This value will also be used by the *cost module* for calculating the *performance cost*.

**mover set max active -queue=p2p**

**Synopsis**

mover set max active -queue=p2p maxActiveP2PTransfers

maxActiveP2PTransfers The maximum number of active pool-to-pool server transfers.

**Description**

Any further requests will be queued. This value will also be used by the *cost module* for calculating the *performance cost*.

**pp set max active**

**Synopsis**

pp set max active maxActivePPTransfers

maxActivePPTransfers The new scaling value for the cost calculation.

**Description**

All pool-to-pool client requests will be performed immediately in order to avoid deadlocks. This value will only used by the *cost module* for calculating the *performance cost*.

**set gap**

**Synopsis**

set gap — Set the gap parameter - the size of free space below which it will be assumed that the pool is full within the cost calculations.
set gap gapPara

gapPara  The size of free space below which it will be assumed that the pool is full. Default is 4GB.

**Description**

The gap parameter is used within the space cost calculation scheme described in the section called “The Space Cost”. It specifies the size of free space below which it will be assumed that the pool is full and consequently the least recently used file has to be removed if a new file has to be stored on the pool. If, on the other hand, the free space is greater than gapPara, it will be expensive to store a file on the pool which exceeds the free space.

**set breakeven**

**set breakeven** — Set the breakeven parameter - used within the cost calculations.

**Synopsis**

set breakeven breakevenPara

breakevenPara  The breakeven parameter has to be a positive number smaller than 1.0. It specifies the impact of the age of the least recently used file on space cost. It the LRU file is one week old, the space cost will be equal to \((1 + \text{breakeven})\). Note that this will not be true, if the breakeven parameter has been set to a value greater or equal to 1.

**Description**

The breakeven parameter is used within the space cost calculation scheme described in the section called “The Space Cost”.

**mover ls**

**mover ls** — List the active and waiting client transfer requests.

**Synopsis**

mover ls [ -queue | -queue=queueName ]

queueName  The name of the mover queue for which the transfers should be listed.

**Description**

Without parameter all transfers are listed. With -queue all requests sorted according to the mover queue are listed. If a queue is explicitly specified, only transfers in that mover queue are listed.

**migration cache**

migration cache — Caches replicas on other pools.
SYNOPSIS

migration cache [options] target...

DESCRIPTION

Caches replicas on other pools. Similar to migration copy, but with different defaults. See migration copy for a description of all options. Equivalent to: migration copy -smode=same -tmode=cached

migration cancel

migration cancel — Cancels a migration job

SYNOPSIS

migration cancel [-force] job

DESCRIPTION

Cancels the given migration job. By default ongoing transfers are allowed to finish gracefully.

migration clear

migration clear — Removes completed migration jobs.

SYNOPSIS

migration clear

DESCRIPTION

Removes completed migration jobs. For reference, information about migration jobs are kept until explicitly cleared.

migration concurrency

migration concurrency — Adjusts the concurrency of a job.

SYNOPSIS

migration concurrency job n

DESCRIPTION

Sets the concurrency of job to n.

migration copy

migration copy — Copies files to other pools.
SYNOPSIS

migration copy [options] target...

DESCRIPTION

Copies files to other pools. Unless filter options are specified, all files on the source pool are copied.

The operation is idempotent, that is, it can safely be repeated without creating extra copies of the files. If the replica exists on any of the target pools, then it is not copied again. If the target pool with the existing replica fails to respond, then the operation is retried indefinitely, unless the job is marked as eager.

Please notice that a job is only idempotent as long as the set of target pools does not change. If pools go offline or are excluded as a result of an exclude or include expression then the job may stop being idempotent.

Both the state of the local replica and that of the target replica can be specified. If the target replica already exists, the state is updated to be at least as strong as the specified target state, that is, the lifetime of sticky bits is extended, but never reduced, and cached can be changed to precious, but never the opposite.

Transfers are subject to the checksum computation policy of the target pool. Thus checksums are verified if and only if the target pool is configured to do so. For existing replicas, the checksum is only verified if the verify option was specified on the migration job.

Jobs can be marked permanent. Permanent jobs never terminate and are stored in the pool setup file with the save command. Permanent jobs watch the repository for state changes and copy any replicas that match the selection criteria, even replicas added after the job was created. Notice that any state change will cause a replica to be reconsidered and enqueued if it matches the selection criteria — also replicas that have been copied before.

Several options allow an expression to be specified. The following operators are recognized: <, <=, ==, !=, >, >=, lt, le, eq, ne, ge, gt, =~, !=, +, -, *, /, %, div, mod, |, & , ^ , ~ , &&, ||, !, and, or, not. : =. Literals may be integer literals, floating point literals, single or double quoted string literals, and boolean true and false. Depending on the context, the expression may refer to constants.

Please notice that the list of supported operators may change in future releases. For permanent jobs we recommend to limit expressions to the basic operators <, <=, ==, !=, >, >=, +, -, *, /, &, |, ! and !.

Options

-accessed=n|[n].[m] Only copy replicas accessed n seconds ago, or accessed within the given, possibly open-ended, interval; e.g. -accessed=0..60 matches files accessed within the last minute; -accessed=60.. matches files accessed one minute or more ago.

-al=ONLINE|NEARLINE Only copy replicas with the given access latency.

-pnfsid=pnfsid[,pnfsid]... Only copy replicas with one of the given PNFS IDs.

-rp=CUSTODIAL|REPLICA|OUTPUT Only copy replicas with the given retention policy.

-size=n|[n].[m] Only copy replicas with size n, or a size within the given, possibly open-ended, interval.
dCache Cell Commands

- **state=cached|precious**  
  Only copy replicas in the given state.

- **sticky[=owner[.owner...]]**  
  Only copy sticky replicas. Can optionally be limited to the list of owners. A sticky flag for each owner must be present for the replica to be selected.

- **storage=class**  
  Only copy replicas with the given storage class.

- **concurrency=concurrency**  
  Specifies how many concurrent transfers to perform. Defaults to 1.

- **order=[-]size[|-]lru**  
  Sort transfer queue. By default transfers are placed in ascending order, that is, smallest and least recently used first. Transfers are placed in descending order if the key is prefixed by a minus sign. Failed transfers are placed at the end of the queue for retry regardless of the order. This option cannot be used for permanent jobs. Notice that for pools with a large number of files, sorting significantly increases the initialization time of the migration job.

  - `size` Sort according to file size.
  - `lru` Sort according to last access time.

- **pins=move|keep**  
  Controls how sticky flags owned by the PinManager are handled:

  - `move` Ask PinManager to move pins to the target pool.
  - `keep` Keep pins on the source pool.

- **smode=same|cached|precious|removable|delete[+owner[.(lifetime)]]...**  
  Update the local replica to the given mode after transfer:

  - `same` does not change the local state (this is the default).
  - `cached` marks it cached.
  - `precious` marks it precious.
  - `removable` marks it cached and strips all existing sticky flags excluding pins.
  - `delete` deletes the replica unless it is pinned. An optional list of sticky flags can be specified. The lifetime is in seconds. A lifetime of 0 causes the flag to immediately expire. Notice that existing sticky flags of the same owner are overwritten.

- **tmode=same|cached|precious[+owner[.(lifetime)]]...**  
  Set the mode of the target replica:

  - `same` applies the state and sticky bits excluding pins of the local replica (this is the default).
  - `cached` marks it cached.
  - `precious` marks it precious.
An optional list of sticky flags can be specified. The lifetime is in seconds.

-verify
Force checksum computation when an existing target is updated.

-eager
Copy replicas rather than retrying when pools with existing replicas fail to respond.

-exclude=pool[.pool...]
Exclude target pools. Single character (?) and multi character (*) wildcards may be used.

-exclude-when=expression
Exclude target pools for which the expression evaluates to true. The expression may refer to the following constants:

source.name or target.name pool name
source.spaceCost or target.spaceCost space cost
source.cpuCost or target.cpuCost cpu cost
source.free or target.free free space in bytes
source.total or target.total total space in bytes
source.removable or target.removable removable space in bytes
source.used or target.used used space in bytes

-only=pool[.pool...]
Only include target pools matching any of the patterns. Single character (?) and multi character (*) wildcards may be used.

-only-when=expression
Only include target pools for which the expression evaluates to true. See the description of -exclude-when for the list of allowed constants.

-refresh=time
Specifies the period in seconds of when target pool information is queried from the pool manager. The default is 300 seconds.

-select=proportional|best|random
Determines how a pool is selected from the set of target pools:

proportional selects a pool with a probability inversely proportional to the cost of the pool.
best selects the pool with the lowest cost.
random selects a pool randomly.
The default is proportional.

-target=pool|pgroup|link
Determines the interpretation of the target names. The default is 'pool'.

-pause-when=expression
Pauses the job when the expression becomes true. The job continues when the expression once again evaluates to false. The following constants are defined for this pool:
queue.files The number of files remaining to be transferred.
queue.bytes The number of bytes remaining to be transferred.
source.name Pool name.
source.spaceCost Space cost.
source.cpuCost CPU cost.
source.free Free space in bytes.
source.total Total space in bytes.
source.removable Removable space in bytes.
source.used Used space in bytes.
targets The number of target pools.

-permanent Mark job as permanent.
-stop-when=expression Terminates the job when the expression becomes true. This option cannot be used for permanent jobs. See the description of -pause-when for the list of constants allowed in the expression.

**migration info**
migration info — Shows detailed information about a migration job.

**SYNOPSIS**
migration info job

**DESCRIPTION**
Shows detailed information about a migration job. Possible job states are:

INITIALIZING Initial scan of repository
RUNNING Job runs (schedules new tasks)
SLEEPING A task failed; no tasks are scheduled for 10 seconds
PAUSED Pause expression evaluates to true; no tasks are scheduled for 10 seconds.
STOPPING Stop expression evaluated to true; waiting for tasks to stop.
SUSPENDED Job suspended by user; no tasks are scheduled
CANCELING Job cancelled by user; waiting for tasks to stop
CANCELLED Job cancelled by user; no tasks are running
FINISHED        Job completed
FAILED          Job failed. Please check the log file for details.

Job tasks may be in any of the following states:

Queued          Queued for execution
GettingLocations Querying PnfsManager for file locations
UpdatingExistingFile Updating the state of existing target file
CancellingUpdate Task cancelled, waiting for update to complete
InitiatingCopy   Request send to target, waiting for confirmation
Copying         Waiting for target to complete the transfer
Pinging          Ping send to target, waiting for reply
NoResponse       Cell connection to target lost
Waiting          Waiting for final confirmation from target
MovingPin        Waiting for pin manager to move pin
Cancelling       Attempting to cancel transfer
Cancelled        Task cancelled, file was not copied
Failed           The task failed
Done             The task completed successfully

migration ls

migration ls — Lists all migration jobs.

SYNOPSIS

migration ls

DESCRIPTION

Lists all migration jobs.

migration move

migration move — Moves replicas to other pools.

SYNOPSIS

migration move [options] target...
dCache Cell Commands

DESCRIPTION
Moves replicas to other pools. The source replica is deleted. Similar to migration copy, but with different defaults. Accepts the same options as migration copy. Equivalent to: migration copy -smode=delete -tmode=same -pins=move

migration suspend

migration suspend — Suspends a migration job.

SYNOPSIS
migration suspend job

DESCRIPTION
Suspends a migration job. A suspended job finishes ongoing transfers, but does not start any new transfer.

migration resume

migration resume — Resumes a suspended migration job.

SYNOPSIS
migration resume job

DESCRIPTION
Resumes a suspended migration job.

PoolManager Commands

rc ls

rc ls — List the requests currently handled by the PoolManager

Synopsis
rc ls [regularExpression] [-w]

Description
Lists all requests currently handled by the pool manager. With the option -w only the requests currently waiting for a response are listed. Only requests satisfying the regular expression are shown.

cm ls

cm ls — List information about the pools in the cost module cache.
Synopsis

```cm ls [-r] [-d] [-s] [fileSize]```

- `-r` Also list the tags, the space cost, and performance cost as calculated by the cost module for a file of size `fileSize` (or zero)
- `-d` Also list the space cost and performance cost as calculated by the cost module for a file of size `fileSize` (or zero)
- `-t` Also list the time since the last update of the cached information in milliseconds.

Description

A typical output reads:

```
(PoolManager) admin > cm ls -r -d -t 12312434442
poolName1={R={a=0;m=2;q=0};S={a=0;m=2;q=0};M={a=0;m=100;q=0};PS={a=0;m=20;q=0};PC={a=0;m=20;q=0};
(...line continues...) SP={t=2147483648;f=924711076;p=1222772572;r=0;1ru=0;{g=20000000;b=0.5}}}
poolName1={Tag={{hostname=hostname}};size=543543543;SC=1.7633947200606475;CC=0.0;}
poolName1=3180

poolName2={R={a=0;m=2;q=0};S={a=0;m=2;q=0};M={a=0;m=100;q=0};PS={a=0;m=20;q=0};PC={a=0;m=20;q=0};
(...line continues...) SP={t=2147483648;f=2147483648;p=0;r=0;1ru=0;{g=4294967296;b=250.0}}}
poolName2={Tag={{hostname=hostname}};size=543543543;SC=0.0030372862312942743;CC=0.0;}
poolName2=3157
```

set pool decision

**set pool decision** — Set the factors for the calculation of the total costs of the pools.

Synopsis

```
set pool decision [-spacecostfactor=scf] [-cpucostfactor=ccf] [-costcut=cc]
```

- `scf` The factor (strength) with which the space cost will be included in the total cost.
- `ccf` The factor (strength) with which the performance cost will be included in the total cost.
- `cc` Deprecated since version 5 of the pool manager.

Description
## Chapter 29. dCache Default Port Values

Table 29.1.

<table>
<thead>
<tr>
<th>Port number</th>
<th>Description</th>
<th>Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>32768 and 32768</td>
<td>is used by the NFS layer within dCache which is based upon rpc. This service is essential for rpc.</td>
<td>NFS</td>
</tr>
<tr>
<td>1939 and 33808</td>
<td>is used by portmapper which is also involved in the rpc dependencies of dCache.</td>

<td>Inbound for GSIIdCap door</td>
</tr>
</tbody>
</table>
Chapter 30. Glossary

The following terms are used in dCache.

**tertiary storage system**
A mass storage system which stores data and is connected to the dCache system. Each dCache pool will write files to it as soon as they have been completely written to the pool (if the pool is not configured as a LFS). The tertiary storage system is not part of dCache. However, it is possible to connect any mass storage system as tertiary storage system to dCache via a simple interface.

**tape backend**
A tertiary storage system which stores data on magnetic tapes.

**Hierarchical Storage Manager (HSM)**
See tertiary storage system.

**HSM Type**
The type of HSM which is connected to dCache as a tertiary storage system. The choice of the HSM type influences the communication between dCache and the HSM. Currently there are osm and enstore. osm is used for most HSMs (TSM, HPSS, ...).

**Large File Store (LFS)**
A Large File Store is the name for a dCache instance that is acting as a filesystem independent to, or in cooperation with, an HSM system. When dCache is acting as an LFS, files may be stored and later read without involving any HSM system.

Whether a dCache instance provides an LFS depends on whether there are pools configured to do so. The LFS option, specified for each pool within the poollist file, describes how that pool should behave. This option can take three possible values:

- **none**
  the pool does not contribute to any LFS capacity. All newly written files are regarded precious and sent to the HSM backend.

- **precious**
  Newly create files are regarded as precious but are not scheduled for the HSM store procedure. Consequently, these file will only disappear from the pool when deleted in the namespace.

- **volatile** (or transient)
  Newly create files are regarded cached and are not scheduled for the HSM store procedure. Though they will never be stored on tape, these file are part of the aging procedure and will be removed as soon as new space is needed.
Note

The volatile lfs mode is deprecated and should not be used.

to store

Copying a file from a dCache pool to the tertiary storage system.

to restore

Copying a file from the tertiary storage system to one of the dCache pools.

to stage

See to restore.

transfer

Any kind of transfer performed by a dCache pool. There are store, restore, pool to pool (client and server), read, and write transfers. The latter two are client transfers.

See Also mover.

mover

The process/thread within a pool which performs a transfer. Each pool has a limited number of movers that may be active at any time; if this limit is reached then further requests for data are queued.

In many protocols, end clients connect to a mover to transfer file contents. To support this, movers must speak the protocol the end client is using.

See Also transfer.

The dCacheSetup File

This is the primary configuration file of a dCache host. It is located at $dcache_home/config/dCacheSetup (typically /etc/dfcache/dCacheSetup). Each domain uses the file config/domainNameSetup which is in fact a symbolic link to config/dCacheSetup. The config/dCacheSetup file might even be the same across the hosts of a dCache instance.

Primary Network Interface

The poollist files are a collection of files in the /etc/dfcache directory. Each poollist file describes the set of pools that should be available for a given node. These files have a filename like hostname.poollist, where hostname is the simple hostname of the node the pools are to run on.

The file consists of one or more lines, with each line describing a pool.

Location Manager

The location manager is a cell that instructs a newly started domains to which domain they should connect. This allows domains to form arbitrary network topologies; although, by default, a dCache instance will form a star topology with the dCacheDomain domain at the centre.

Cell

A cell is a collection of Java threads that provide a discrete and simple service within dCache. Each cell is hosted within a domain.

Cells have an address derived from concatenating their name, the @ symbol and their containing domain name.
Domain
A domain is a collection of one or more cells that provide a set of related services within a dCache instance. Each domain requires its own Java Virtual Machine. A typical domain might provide external connectivity (i.e., a door) or manage the pools hosted on a machine.

Each domain has at least one cell, called the System cell and many tunnel cells for communicating with other Domains. To provide a useful service, a domain will contain other cells that provide specific behaviour.

Door
Door is the generic name for special cells that provides the first point of access for end clients to communicate with a dCache instance. There are different door implementations (e.g., GSIdCap door and GridFTP door), allowing a dCache instance to support multiple communication protocols.

A door will (typically) bind to a well-known port number depending on the protocol the door supports. This allows for only a single door instance per machine for each protocol.

A door will typically identify which pool will satisfy the end user’s operation and redirect the client to the corresponding pool. In some cases this is not possible; for example, some protocols (such as GridFTP version 1) do not allow servers to redirect end-clients, in other cases pool servers may be behind a firewall, so preventing direct access. When direct end-client access is not possible, the door may act as a data proxy, streaming data to the client.

By default, each door is hosted in a dedicated domain. This allows easy control of whether a protocol is supported from a particular machine.

Java Virtual Machine (JVM)
Java programs are typically compiled into a binary form called Java byte-code. Byte-code is comparable to the format that computers understand native; however, no mainstream processor understands Java byte-code. Instead compiled Java programs typically require a translation layer for them to run. This translation layer is called a Java Virtual Machine (JVM). It is a standardised execution environment that Java programs may run within. A JVM is typically represented as a process within the host computer.

Well Known Cell
A well-known cell is a cell that registers itself centrally. Within the admin interface, a well-known cell may be referred to by just its cell name.

Pinboard
The pinboard is a collection of messages describing events within dCache and is similar to a log file. Each cell will (typically) have its own pinboard.

Breakeven Parameter

## Default Mover Queue

### Namespace

The namespace is a core component of dCache. It maps each stored file to a unique identification number and allows storing of metadata against either files or directories.

DCache supports two (independent) namespace implementations: *pn-\text{fs}* and *Chimera*.

### pnfs filesystem

*pnfs* is a filesystem that uses a database to store all information, including the contents of files. This filesystem is made available via NFS, so authorised hosts can mount *pnfs* and use it like any other file system.

DCache may use *pnfs* as its namespace. Although it is possible to store file contents in *pnfs*, DCache does not do this. Instead, DCache stores the file data on one (or more) pools.

*pnfs* includes some unique additional properties. These include *commands*, *pnfs IDs*, *levels*, *directory tags* and *wormholes*.

### pnfs dot command

To configure and access some of the special features of the *pnfs* filesystem, special files may be read, written to or created. These files all start with a dot (or period) and have one or more parameters after, each parameter is contained within a set of parentheses; for example, the file `. (tag) (foo)` is the *pnfs* dot command for reading or writing the *foo directory tag* value.

Care must be taken when accessing a dot command from a shell. Shells will often expand parentheses so the filename must be protected against this; for example, by quoting the filename or by escaping the parentheses.

### pnfs level

In *pnfs*, each file can have up to eight independent contents; these file-contents, called levels, may be accessed independently. DCache will store some file metadata in levels 1 and 2, but DCache will not store any file data in *pnfs*.

### pnfs directory tag

*pnfs* includes the concept of tags. A tag is a keyword-value pair associated with a directory. Subdirectories inherit tags from their parent directory. New values may be assigned, but tags cannot be removed. The *dot command* `. (tag) (foo)` may be used to read or write tag *foo*’s value. The *dot command* `. (tags) ()` may be read for a list of all tags in that file’s subdirectory.

More details on directory tags are given in the section called “Directory Tags”.

### pnfs ID

Each component (file, directory, etc) in a *pnfs* instance has a unique ID: a 24-digit hexadecimal number. This unique ID is used in DCache to refer to files without knowing the component’s name or in which directory the component is located.

More details on *pnfs* IDs are given in the section called “pnfsIDs”.

<thead>
<tr>
<th>Glossary</th>
<th>Outdated</th>
<th>Outdated</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pool to Pool Transfer</strong></td>
<td>A pool-to-pool transfer is one where a file is transferred from one dCache pool to another. This is typically done to satisfy a read request, either as a load-balancing technique or because the file is not available on pools that the end-user has access.</td>
<td></td>
</tr>
<tr>
<td><strong>Storage Class</strong></td>
<td>The storage class is a string of the form $\text{StoreName:StorageGroup@type-of-storage-system}$ containing exactly one @-symbol.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• $\text{StoreName:StorageGroup}$ is a string describing the storage class in a syntax which depends on the storage system.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• $\text{type-of-storage-system}$ denotes the type of storage system in use.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In general use $\text{type-of-storage-system}=\text{osm}$.</td>
</tr>
<tr>
<td></td>
<td>A storage class is used by a tertiary storage system to decide where to store the file (i.e. on which set of tapes). dCache can use the storage class for a similar purpose, namely to decide on which pools the file can be stored.</td>
<td></td>
</tr>
<tr>
<td><strong>batch File</strong></td>
<td>A batch file describes which cells in a domain are to be started and with what options. They typically have filenames from combining the name of a domain with .batch; for example, the dCacheDomain domain has a corresponding batch file dCache.batch.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Although the cells in a domain may be configured by altering the corresponding batch file, most typical changes can be altered by editing the dCacheConfig file and this is the preferred method.</td>
</tr>
<tr>
<td><strong>Context</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Wormhole</strong></td>
<td>A wormhole is a feature of the pnfs filesystem. A wormhole is a file that is accessible in all directories; however, the file is not returned when scanning a directory (e.g., using the ls command).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>More details on wormholes are given in the section called “Global Configuration with Wormholes”.</td>
<td></td>
</tr>
<tr>
<td><strong>Chimera</strong></td>
<td>Chimera is a namespace implementation that is similar to pnfs but provides better integration with a relational database. Because of this, it allows additional functionality to be added, so some dCache features require a chimera namespace.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Many pnfs features are available in Chimera, including levels, directory tags and many of the dot commands.</td>
<td></td>
</tr>
<tr>
<td><strong>Chimera ID</strong></td>
<td>A Chimera ID is a 36 hexadecimal digit that uniquely defines a file or directory. It’s equivalent to a pnfs ID.</td>
<td></td>
</tr>
<tr>
<td>Glossary</td>
<td>Definition</td>
<td></td>
</tr>
<tr>
<td>----------</td>
<td>-----------</td>
<td></td>
</tr>
<tr>
<td>Replica</td>
<td>It is possible that dCache will choose to make a file accessible from more than one pool using a pool-to-pool copy. If this happens, then each copy of the file is a replica. A file is independent of which pool is storing the data whereas a replica is uniquely specified by the pnfs ID and the pool name it is stored on.</td>
<td></td>
</tr>
<tr>
<td>Precious Replica</td>
<td>A precious replica is a replica that should be stored on tape.</td>
<td></td>
</tr>
<tr>
<td>Cached Replica</td>
<td>A cached replica is a replica that should not be stored on tape.</td>
<td></td>
</tr>
<tr>
<td>Replica Manager</td>
<td>The replica manager keeps track of the number of replicas of each file within a certain subset of pools and makes sure this number is always within a specified range. This way, the system makes sure that enough versions of each file are present and accessible at all times. This is especially useful to ensure resilience of the dCache system, even if the hardware is not reliable. The replica manager cannot be used when the system is connected to a tertiary storage system. The activation and configuration of the replica manager is described in Chapter 7, The replica Service (Replica Manager).</td>
<td></td>
</tr>
<tr>
<td>Storage Resource Manager (SRM)</td>
<td>An SRM provides a standardised webservice interface for managing a storage resource (e.g. a dCache instance). It is possible to reserve space, initiate file storage or retrieve, and replicate files to another SRM. The actual transfer of data is not done via the SRM itself but via any protocol supported by both parties of the transfer. Authentication and authorisation is done with the grid security infrastructure. dCache comes with an implementation of an SRM which can turn any dCache instance into a grid storage element.</td>
<td></td>
</tr>
<tr>
<td>pnfs Companion</td>
<td>The pnfs companion is a (database) table that stores dCache specific information; specifically, on which pools a file may be found. dCache can operate without a companion and will store file location information within a level. Storing replica location information in the companion database greatly improves the performance of dCache as the location information is often queried by the pool manager. Although a companion database may be used with Chimera, doing so provides no performance improvements and is not recommended.</td>
<td></td>
</tr>
<tr>
<td>Billing/Accounting</td>
<td>Accounting information is either stored in a text file or in a PostgreSQL database by the billing cell usually started in the httpdDomain domain. This is described in Chapter 24, Accounting.</td>
<td></td>
</tr>
<tr>
<td>Pool Manager</td>
<td>The pool manager is the cell running in the dCacheDomain domain. It is a central component of a dCache instance and decides which pool is used for an incoming request.</td>
<td></td>
</tr>
<tr>
<td>Cost Module</td>
<td>The cost module is a Java class responsible for combining the different types of cost associated with a particular operation; for example, if a file is to be stored, the cost module will combine the storage costs and CPU costs for each candidate target pool. The pool manager will choose the candidate pool with the least combined cost.</td>
<td></td>
</tr>
<tr>
<td>Term</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Pool Selection Unit</td>
<td>The pool selection unit is a Java class responsible for determining the set of candidate pools for a specific transaction. A detailed account of its configuration and behaviour is given in the section called “The Pool Selection Mechanism”.</td>
<td></td>
</tr>
<tr>
<td>Pin Manager</td>
<td>The pin manager is a cell by default running in the utility domain. It is a central service that can “pin” files to a pool for a certain time. It is used by the SRM to satisfy prestage requests.</td>
<td></td>
</tr>
<tr>
<td>Space Manager</td>
<td>The (SRM) Space Manager is a cell by default running in the srm domain. It is a central service that records reserved space on pools. A space reservation may be either for a specific duration or never expires. The Space Manager is used by the SRM to satisfy space reservation requests.</td>
<td></td>
</tr>
<tr>
<td>Pool</td>
<td>A pool is a cell responsible for storing retrieved files and for providing access to that data. Data access is supported via movers. A machine may have multiple pools, perhaps due to that machine’s storage being split over multiple partitions.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>A pool must have a unique name and all pool cells on a particular machine are hosted in a domain that derives its name from the host machine’s name.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The list of directories that are to store pool data are found in the pool-list File, which is located on the pool node.</td>
<td></td>
</tr>
<tr>
<td>Sweeper</td>
<td>A sweeper is an activity located on a pool. It is responsible for deleting files on the pool that have been marked for removal. Files can be marked for removal because their corresponding namespace entry has been deleted or because the local file is a cache copy and more disk space is needed.</td>
<td></td>
</tr>
<tr>
<td>HSM Sweeper</td>
<td>The HSM sweeper, if enabled, is a component that is responsible for removing files from the HSM when the corresponding namespace entry has been removed.</td>
<td></td>
</tr>
<tr>
<td>Cost</td>
<td>The pool manager determines the pool used for storing a file by calculating a cost value for each available pool. The pool with the lowest cost is used. The costs are calculated by the cost module as described in . The total cost is a linear combination of the I.e.,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>where ccf and scf are configurable with the command set pool decision.</td>
<td></td>
</tr>
<tr>
<td>Performance Cost</td>
<td>See Also gl-cost.</td>
<td></td>
</tr>
<tr>
<td>Space Cost</td>
<td>See Also gl-cost.</td>
<td></td>
